SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its bulletin, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

To join SSAR or to renew your membership, please visit the secure online ZenScientist website via this link:
http://www.ssarherps.org/pages/membership.php

Future Annual Meetings
2016 — New Orleans, Louisiana 6–10 July (JMIH with ASIH and HL)

A Summary and Discussion of Helminth Parasites Reported from Xantusiid Lizards with a New Nematode Record from *Lepidophyma smithii* (Squamata: Xantusiidae)

The xantusiid genus *Lepidophyma* is composed of 19 currently recognized species scattered from Nuevo León, Mexico south to Panama (Bezy and Camarillo 2002; Canseco-Márquez et al. 2008; García-Vázquez et al. 2010). Many of these are known from very few specimens and localities and their helminth parasites remain poorly known. Here we provide a summary of helminths reported from *Lepidophyma* and *Cricosaura* and discuss helminth parasitism in the Xantusiidae. We also report the results of a helminthological examination of Smith's Tropical Night Lizard, *Lepidophyma, smithii* Bocourt, 1876 (Fig. 1) from Chiapas, Mexico. This species is exceptional in the Xantusiidae in having a relatively broad ecological and latitudinal distribution, occurring in caves, rock crevices, and rotting logs along the Pacific versant from Guerrero, Mexico, south through Guatemala to El Salvador (Fig. 2) (Bezy and Camarillo 2002; Mendoza-Hernández and Santos-Barrera 2004). Previously, the only helminths known from *L. smithii* are two species of Nematoda, *Parapharyngodon guerreroensis* Bursey and Goldberg, 2015 and third stage larvae of *Physaloptera* sp. found in specimens from Guerrero and Oaxaca (Bursey and Goldberg 2015).

Methods

Nine *Lepidophyma smithii* (mean snout–vent length [SVL] = 72.7 mm ± 5.5 SD, range = 66–84 mm) from Chiapas, Mexico in the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California were examined: LACM 100666–100668, 101263, from 48 km NW Huixtla (15.1333°N, 92.4667°W; WGS 84), 30 June 1968; LACM 136359–136361, 136362, 136364 from 8.2 km NE Escuintla (15.3333°N, 92.63333°W; WGS 84), 17 July 1984.

*Corresponding author; e-mail: sgoldberg@whittier.edu

The body cavity was opened and the esophagus, stomach, small intestine, and large intestine were slit using a razor blade, and the contents examined under a dissecting microscope. Only nematodes were found. Nematodes were assigned to genus based upon the keys of Anderson et al. (2009) and Gibbons (2010) and comparison with nematodes from the original descriptions (Bursey et al. 2006). Each nematode was cleared in a drop of lactophenol on a microscope slide, cover slipped, examined under a compound microscope and identified. Voucher nematodes were deposited in the Harold W. Manter Laboratory (HWML), University of Nebraska, Lincoln, USA as *Aplectana herediaensis* (HWML 92091). Parasite terminology is according to Bush et al. (1997).

Results

All nine *L. smithii* from Chiapas were found to be infected with the nematode *Aplectana herediaensis* (prevalence = number infected [9]/number examined [9] = 100%). A total of 577 nematodes was recovered, with a mean intensity of infection (mean number nematodes per infected host) = 65.2 ± 45.2 SD, range = 5–149. No other nematodes were seen.

Discussion

Summary of helminths known from Lepidophyma.—A total of 15 species of helminths (13 Nematoda, 1 Cestoda, 1 Digenea) are known from the seven species of *Lepidophyma* examined to date (Table 1). Summarized below are their hosts and geographic

PHOTO BY ROBERT L. BEZY

Fig. 1. *Lepidophyma smithii* (Smith's Tropical Night Lizard), LACM 135511, female, SVL 92 mm) from Chiapas, Mexico.

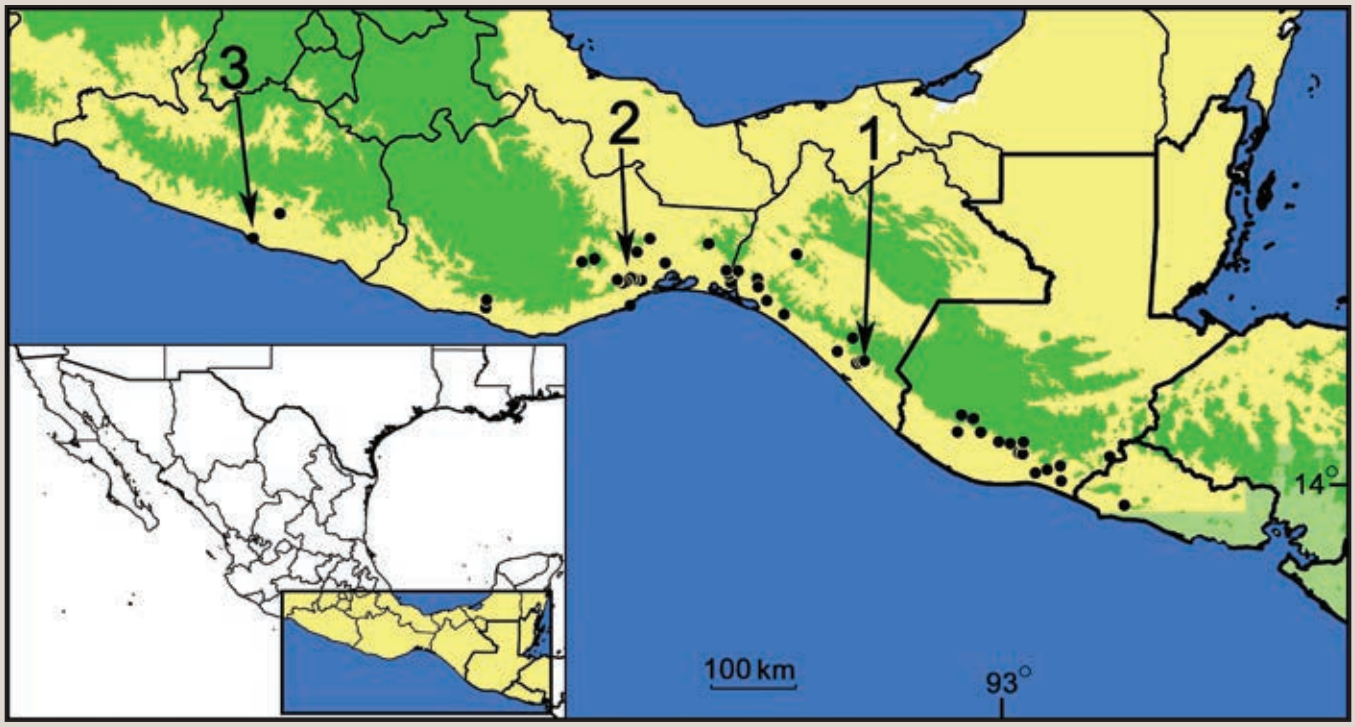

FIG. 2. Geographic distribution of *Lepdophyma smithii* based on museum specimens (listed by Bezy and Camarillo 2002; Mendoza-Hernández and Santos-Barrera 2004). Green indicates elevation greater than 500 m. Arrows indicate areas in Mexico from which helminths have been recovered: 1) NW of Escuintla, Chiapas; 2) W of Tehuantepec, Oaxaca; 3) vicinity of Puerto Marqués, Guerrero.

distributions, life histories, modes of transmission, and known host occurrences in amphibians and reptiles.

The nematode *Aplectana herediaensis* was described from *L. flavimaculatum* from Costa Rica by Bursey et al. (2006). *Aplectana* is a taxon of the Cosmocercidae, which infect directly (monoxenous), either by ingestion or skin penetration (Anderson 2000). It has been reported only from *Lepidophyma* and has been found in all species examined to date, except *L. gaigeae* (Table 1) for which 57 specimens from Hidalgo and Queretaro, Mexico were examined by Goldberg et al. (2002, 2014a). *Lepidophyma gaigeae* occupies a habitat that is unique in the genus, living in limestone crevices in pine-oak woodland of the Sierra Madre Oriental (Bezy and Camarillo 2002; Leavitt and Hibbitts 2012). Infection by *A. herediaensis* was found at high prevalence (9/9) and mean intensity (65.2) in *L. smithii* from Chiapas, where the lizards live in wet decaying logs. That *A. herediaensis* was not recovered from specimens of *L. smithii* from Guerrero (N = 4) and Oaxaca (N = 2) may be an artifact of small number of lizards examined (Bursey and Goldberg 2015) or may reflect habitat in the region (caves, rock-crevices, and road culverts) (Bezy and Camarillo 2002).

The nematode *Africana telfordi* was described from the hoplocercid lizard, *Enyalioides heterolepis* from Panama by Bursey and Goldberg (2002). It also occurs in *Basiliscus plumifrons* (Goldberg and Bursey 2009a) and *L. flavimaculatum* and *L. reticulatum* from Costa Rica (Table 1) (Goldberg and Bursey 2011). *Africana* is a taxon of Heterakidae; infection is direct and occurs when the host ingests an egg (Anderson 2000).

In the genus *Parapharyngodon, P. alvarengai* was reported in *L. sylvaticum* from Hidalgo and Nuevo Leon, Mexico (Goldberg et al. 2014b). It is a generalist nematode occurring in lizards of diverse families Dactyloidae, Gekkonidae, Phrynosomatidae, Scincidae, Teiidae as well as the toad *Rhinella icterica* (Goldberg et al. 2014b). *Parapharyngodon colonensis* was described from *L. flavimaculatum* from Colon Province, Panama by Bursey et al. (2007), which is the only host known for this nematode. *Parapharyngodon guerreroensis* was described from *L. smithii* from Guerrero and Oaxaca, Mexico by Bursey and Goldberg (2015). It is the only host known for this nematode. Life cycles of members of the genus *Parapharyngodon* remain poorly known. *Parapharyngodon* is a taxon of the Pharyngodonidae and members of this order are strictly monoxenous (Anderson 2000).

Raillietnema brachyspiculatum was described from *L. tuxtlae* from Veracruz, Mexico by Bursey et al. (1998) and was also reported from *L. flavimaculatum* from Costa Rica (Goldberg and Bursey 2011). It is a member of the Cosmocercidae; infection is direct and occurs by egg ingestion or skin penetration (Anderson 2000).

Both *Spauligodon giganticus* and *S. oxkutzcabiensis* were found in *L. gaigeae* from Mexico (Goldberg et al. 2002; 2014a). *Spauligodon giganticus* is widely distributed in North America; a host list was provided by Bursey and Goldberg (1992). Additional hosts are in Goldberg et al. (2003). *Spauligodon oxkutzcabiensis* is known from lizards of the families Gekkonidae, Phrynosomatidae and Tropiduridae from Mexico, Costa Rica, Panama and Peru (Goldberg et al. 2003; Bursey et al. 2007; Goldberg and Bursey, 2009b). *Spauligodon* is a taxon of the Pharyngodonidae and members of this family are strictly monoxenous (Anderson 2000).

Strongyluris panamaensis was found in *L. flavimaculatum* from Panama by Bursey et al. (2007) and was described from *Anolis biporcatus* (Dactyloidae) from Panama by Bursey et al. (2003). *Strongyluris* is a taxon of the Heterakidae and members of this family are monoxenous; eggs containing the infective stage are ingested by the host (Anderson 2000).

Three nematode species were found as larvae (Table 1). None of them complete development in lizards, which likely serve as transport (paratenic) hosts. Development to the adult

TABLE 1. Helminth species, localities, and sources reported for species of *Lepidophyma* and *Cricosaura*.

Helminth species	*Lepidophyma, Cricosaura* species	Locality	Source
Digenea			
Mesocoelium sp.	*L. flavimaculatum*	Costa Rica	Bursey et al. 2006; Goldberg and Bursey 2011
		Panama	Bursey et al. 2007
Cestoda

Spauligodon giganticus	*L. gaigeae*	Mexico: Hidalgo	Goldberg et al. 2002
S. oxkutzcabiensis	*L. gaigeae*	Mexico: Queretaro	Goldberg et al. 2014a
Strongyluris panamaensis	*L. flavimaculatum*	Panama	Bursey et al. 2007
Ascarididae gen. sp. (larvae)	*L. gaigeae*	Mexico: Hidalgo	Goldberg et al. 2002
	L. sylvaticum	Mexico: Hidalgo, Nuevo León	Goldberg et al. 2014b
Contracaecum sp. (larvae)	*L. flavimaculatum*	Costa Rica	Goldberg and Bursey 2011
Physaloptera sp. (3rd stage larvae)	*L. sylvaticum*	Mexico: Hidalgo, Nuevo León	Goldberg et al. 2014b
Skrjabinodon cricosaurae	*C. typica*	Cuba	Barus and Coy Otero 1974; Goldberg et al. 1998b

occurs when the lizard is eaten by a carnivore. Members of the Ascarididae use invertebrates for transmission of second-stage larvae and vertebrates for transmission of third-stage larvae (Anderson 2000). The definitive hosts of *Contracaecum* are piscivorous birds and mammals (Anderson 2000). *Physaloptera* is widespread in amphibians and reptiles (Goldberg et al. 1993b).

The digenean *Mesocoelium* sp. was reported from *L. flavimaculatum* from Costa Rica (Bursey et al. 2006; Goldberg and Bursey 2011) and Panama (Bursey et al. 2007). Formerly any specimens of *Mesocoelium* reported from amphibians or reptiles worldwide were referred to as *M. monas* (Dronen et al. 2012). Recently Calhoun and Dronen (2012) reevaluated specimens previously identified as *M. monas* and proposed keys to some 43 species. Terrestrial mollusks serve as intermediate hosts; however, cercariae emerging from snails encyst readily on any object they happen to settle on and such metacercariae from substrate have been used successfully in infestation experiments of agamid lizards (Thomas 1965).

The cestode *Bitegmen gerrhonoti* (Nematotaeniidae) was originally described as *Baerietta gerrhonoti* by Telford (1965) from the Southern Alligator Lizard, *Elgaria multicarinata* (as *Gerrhonotus multicarinatus*) from California. This cestode was reassigned to *Bitegmen* by Jones (1987). It is also known from the plethodontid salamander *Ensatina eschscholtzii* from southern California (Goldberg et al. 1998a). The life cycle of *B. gerrhonoti* is unknown, but Joyeux (1927) regards the life history of nematotaeniid cestodes to be direct; a new host becomes infected by digestion of eggs.

Overview of helminths in the Xantusiidae.—The helminths reported from *Xantusia* (summary in Goldberg et al. 2015), *Cricosaura* and *Lepidophyma* (Table 1) support that xantusiid lizards are parasitized mainly by nematodes with direct life cycles (monoxenous) (Anderson 2000). For *Lepidophyma* this includes: *Africana telfordi, Aplectana herediaensis, Parapharyngodon alvarengai, P. colonensis, P. guerreroensis, Raillietnema brachyspiculatum, Spauligodon giganticus, S. oxkutzcabiensis,* and *Strongyluris panamaensis* (Table 1). The nematode *Skrjabinodon cricosaurae,* the only parasite known from *Cricosaura typica* (Coy Otero and Barus 1979), and six of seven nematode species known from *Xantusia* (summary in Goldberg et

al. 2015): *Alaeuris clementensis, A. riversianae, Parapharyngodon bicaudatus, P. californiensis, P. pseudothaparius,* and *P. xantusi* have direct life cycles. Xantusiids may be active foragers (Cooper 2000) but the paucity of observations of the lizards active abroad suggests that foraging is primarily restricted to the confines of their microhabitats, which consist of logs, caves, rock-crevices, and rocks on soil (summary in Bezy 1989). It appears this reclusive life style and narrow foraging mode favors infection by Nematoda with direct life cycles in which infection likely occurs during feeding by ingestion of eggs in fecal contaminated soil. Goldberg and Bursey (1992) reported that 74% of *Sceloporus jarrovii* neonates between one day and two weeks of age were infected with eggs or larvae of the nematode *S. giganticus,* which has a direct life cycle.

Moreover, there is a tendency for species of the Xantusiidae to be parasitized by nematodes known only in members of this family: *A. herediaensis* (restricted to *Lepidophyma*), *S. cricosaurae* (restricted to *Cricosaura*), *Alaeuris clementensis, A. riversianae, Parapharyngodon bicaudatus, P. californiensis, P. pseudothaparius, P. xantusi* (restricted to *X. riversiana*). This contrasts with wide-ranging species of Dactyloidae, Phrynosomatidae, and Teiidae, which have greater opportunities for ingestion of insect intermediate hosts containing larvae of nematodes with indirect (heteroxenous) life cycles. They are consequently frequently parasitized by generalist nematodes that infect a variety of lizards (Baker 1987). In some cases the limited number of host species reported for the helminths infecting xantusiid lizards may reflect the small number of helminthological surveys conducted on xantusiids and other tropical lizards. However, in their survey of 1412 lizard specimens from Cuba representing 53 species, Coy Otero and Barus (1979) recovered *S. cricosaurae* only in *C. typica*. The presence of only one species of helminth in this Cuban endemic lizard may reflect its narrow foraging in tunnels under rocks (summary in Fernández de Acrila et al. 2012).

The occurrence of endemic nematodes found only in *X. riversiana* (four of five species) might reflect the geographic isolation of this species on the California Channel Islands (Goldberg et al. 1993a, 2015). The moist maritime climate, overlapping home ranges, and extremely dense populations of *X. riversiana* (Fellers and Drost 1991; Mautz 1993) might promote infection by monoxenous nematodes.

Again, it is conceivable that the sedentary life styles and small home ranges of xantusiids might limit their contact with the intermediate hosts needed to complete heteroxenous life cycles. Considering infections of xantusiids by heteroxenous parasites, *Oochoristica* cestodes have been reported (Goldberg et al. 2015). Conn (1985) reported that tenebrionid beetles served as intermediate hosts for the congener *Oochoristica anolis*. The life cycle of the heteroxenous nematode *Thubunaea iguanae,* found in *X. riversiana* (Goldberg et al. 1993a) and *X. wigginsi* (Goldberg et al. 2015) is unknown; however, Velikanov (1992) reported tenebrionid beetles served as intermediate hosts for the congener *T. baylisi*. Given the encystment on substrate of metacercariae of *Mesocoelium*, after release of cercariae by snails (Thomas 1965), infection may not require ingesting an intermediate host, thus for xantusiids infection by *Mesocoelium* may be more monoxenic-like.

None of the helminth species (monoxenous or heteroxenous) reported to date in xantusiids is shared among *Cricosaura, Lepidophyma*, or *Xantusia*. This is consistent with the ancient divergences (Noonan et al. 2013) and differences in geographic, vegetation, and climatic distributions of the genera, and with the microhabitat restrictions, small home ranges, and philopatry of the lizards (summary in Bezy 1989).

Acknowledgments.—We thank G. Pauly (LACM) for permission to examine *L. smithii*.

Natural History Notes on a Northern Population of the Milksnake (*Lampropeltis triangulum*), with Evidence for Ontogenetic Shifts in Cover Use and Diet

Some widely distributed species are generally common throughout their geographic ranges and are consequently well studied (e.g., Common Gartersnake, *Thamnophis sirtalis*). Others are less abundant (or at least less conspicuous) and therefore, despite their wide range, are relatively understudied. One example of such a species is the Milksnake, *Lampropeltis triangulum*, which ranges from southern Canada into South America (Navarrete and Rodríguez-Acosta 2003). This species has been subdivided into numerous subspecies, reflecting the highly variable nature of its color and pattern (Navarrete and Rodríguez-Acosta 2003). In fact, *L. triangulum* is likely a non-monophyletic group of multiple species (Ruane et al. 2014), but I leave that issue aside here. In parts of their range, Milksnakes are especially well known as mimics of venomous coral snakes (Harper and Pfennig 2007). Habitat selection and thermoregulation of Milksnakes have been well studied in the northeastern part of their range (Row and Blouin-Demers 2006a,b), but studies of other aspects of their ecology have been limited (e.g., Fitch and Fleet 1970; Hamilton et al. 2012). The most detailed report of their general ecology is from a very long-term study from Kansas (Fitch 1999).

Species with wide ranges often exhibit significant local and broader-scale geographic variation in life-history traits (Gregory and Larsen 1993, 1996; Tuttle and Gregory 2012), food habits (Gregory and Nelson 1991; Gregory and Isaac 2004), and other aspects of their ecology (e.g., movements: Macartney et al. 1988; Lawson 1994), presumably reflecting phenotypic plasticity and/or adaptation to local conditions. Therefore, it is important to record the natural history of such species at diverse localities throughout their geographic range to facilitate eventual comparisons. Here, I document size distributions, sexual dimorphism, patterns of cover use, and feeding habits of Milksnakes based on a small sample from a population near the northern limit of the species' range in southern Ontario, Canada.

Materials and methods.—I collected data on Milksnakes from 1988–2008 during a long-term study of an assemblage of six species of snakes along Sixteen Mile Creek in Oakville, Ontario (53.3500°N, 112.9167°W). The study site consisted of an approximately 14.5-km stretch of creek valley. I searched for snakes mainly in the valley bottom, especially along the creek, where rocks used as cover by snakes are abundant (Gregory 2004a, 2009), but occasionally also on the valley sides and uplands. I searched during daylight hours, capturing snakes both in the open and under cover objects. I measured the snout–vent length (SVL) and mass of captured snakes, determined their sex, and gently forced snakes with food to regurgitate prey; when possible, I carefully returned prey to the snake before releasing the snake. I also individually marked each snake before release by clipping a unique combination of subcaudal scutes. I used SAS 9.3 to do statistical analyses with an α-level of 0.05.

Results.—I captured a total of 33 Milksnakes during the course of the study; none was ever recaptured. Thirteen of these snakes were male and 20 were female; I scored only one female (477 mm SVL) as possibly gravid, but could not ascertain her reproductive status definitively. Snakes ranged in SVL from 232–810 mm with no significant difference between the sexes (Fig. 1; Kruskal-Wallis test, $\chi^2 = 0.782$, $P = 0.38$). Excluding the possibly gravid female, I obtained measures of mass for 27 snakes, which ranged from 3–160 g. There was no significant difference in relative mass between the sexes (i.e., mass at a given SVL). I tested this by analysis of covariance of mass between the sexes with SVL as a covariate; both mass and SVL were log-transformed for this analysis. The interaction term was non-significant ($F_{1,23} = 2.16$, $P = 0.16$; Type III sum of squares). I therefore redid the analysis including only the main effects; that analysis showed that mass was positively related to SVL ($F_{1,24} = 1006.45$, $P < 0.0001$), but did

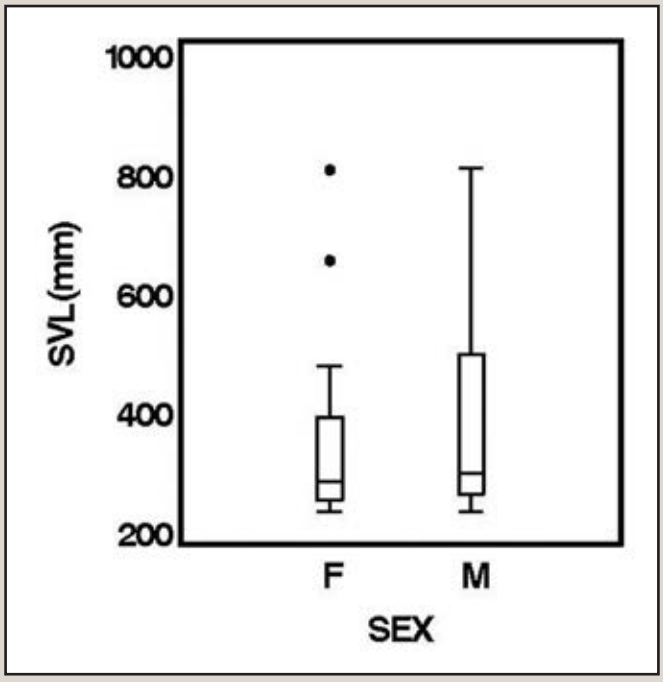

FIG. 1. Boxplots of distribution of snout–vent lengths (SVL) of female (N = 20) and male (N = 13) Milksnakes (*Lampropeltis triangulum*). Upper and lower boundaries of each box represent quartiles (i.e., 25th and 75th percentiles); horizontal line in box is median. Whiskers (vertical lines from box) extend to farthest value not exceeding 1.5 times the distance between the quartiles; more distant values are represented by dots.

not differ between the sexes ($F_{1,24}$ = 0.83, P = 0.37). I then pooled the two sexes and calculated the slope of the Reduced Major Axis regression; I tested that slope against a null-hypothesis value of 3, representing isometry (Gregory 2004b), and found no significant difference (t_{25} = -1.63, P = 0.12).

The two largest snakes in the sample, one male (810 mm SVL) and the other female (807 mm SVL) were found under adjacent touching rocks. These two large snakes were the only ones showing any sign of injury; both were missing the tips of their tails.

The majority of snakes (29/33) were found under cover rather than in the open, but there was nevertheless a statistically significant trend for larger snakes to be found more often in the open. I determined this via a logistic regression of capture location (in open vs. under cover) against SVL, using the EXACT option for small samples, and found a significant relationship (Score = 5.87, P = 0.016; Fig. 2).

Only six snakes yielded prey, too small a sample for any formal analysis; one additional snake contained unidentified prey (a small lump that I could not coax the snake to regurgitate). Two larger snakes contained rodents (Fig. 3). One of these had three nestling pups in its gut (determined by palpation; only one removed) and the other had the posterior part of a small furred vole in its gut; both prey that I examined had been swallowed headfirst (assuming no change of orientation of the prey in the gut post-swallowing). Four snakes, ranging fairly widely in size (Fig. 3), had each eaten a single DeKay's Brownsnake (*Storeria dekayi*), all of which had been swallowed headfirst. One of the *Storeria* was almost the same length and mass as the Milksnake that ate it (Fig. 4). When first observed, that Milksnake had a misshapen body with numerous lumps where the *Storeria* was kinked inside its gut (see figure 1c in Jackson et al. 2004 for a similar example); the tail of the *Storeria* was folded in the Milksnake's throat. Almost immediately after I captured it, the snake began to regurgitate its prey. In addition to measuring the SVL and mass of this prey item (Fig. 4), I measured its tail length and also was able to measure tail lengths of two of the other *Storeria* that had been swallowed by Milksnakes. Although I could not account for possible sexual dimorphism of tail length of *Storeria*, these data suggest a positive correlation between size of Milksnake (SVL 251, 261, 477 mm) and size of snake prey (tail length 50, 68, 75 mm, respectively).

Discussion.—Despite small sample size, a number of conclusions can be reached and potential trends identified from the data presented here. First, Milksnakes at my study site reach similar maximum body sizes to those reached in Kansas (Fitch and Fleet 1970; Fitch 1999) and Illinois (Dyrkacz 1977), although the latter used total length rather than SVL. Milksnakes in Latin America reach somewhat greater maximum SVL (Rodríguez and Drummond 2000; Navarrete and Rodríguez-Acosta 2003). Row and Blouin-Demers (2006b) did not present SVLs of their radiotracked snakes in Ontario, but their minimum mass of 130 g corresponds to the largest snakes in my sample. The smallest snakes that I found were within the size range for hatchlings reported by Dyrkacz (1977) and Fitch (1999) and the possibly gravid female that I recorded was slightly smaller than the minimum size of gravid female (514 mm SVL) reported by Fitch (1999). Second, I found no evidence of sexual dimorphism in size or relative body mass nor of allometric growth with respect to mass. Other studies of Milksnakes have found that

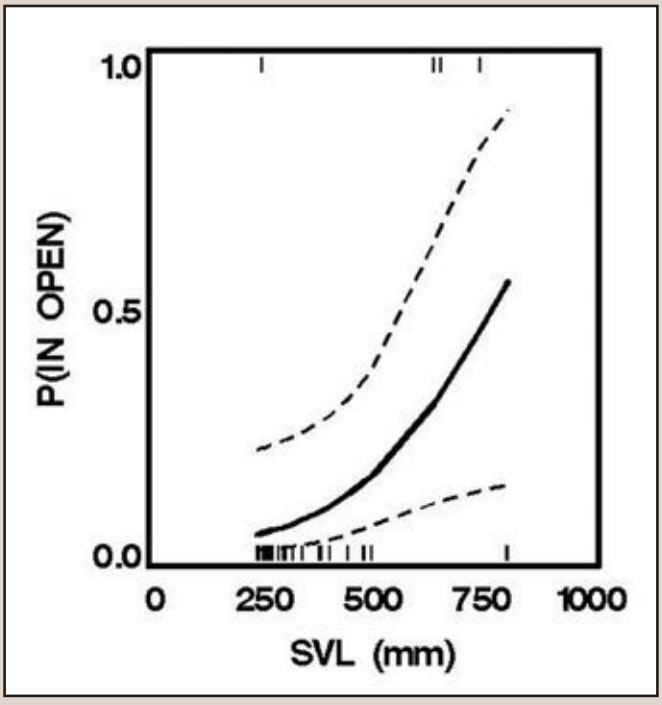

FIG. 2. Plot of logistic regression of probability of being in the open (vs. under cover), P(in open), against snout–vent length (SVL) for 33 Milksnakes (*Lampropeltis triangulum*). Short vertical lines at top and bottom are data (i.e., in open or under cover), solid line is predicted regression, and dashed lines are 95% confidence limits on predicted line.

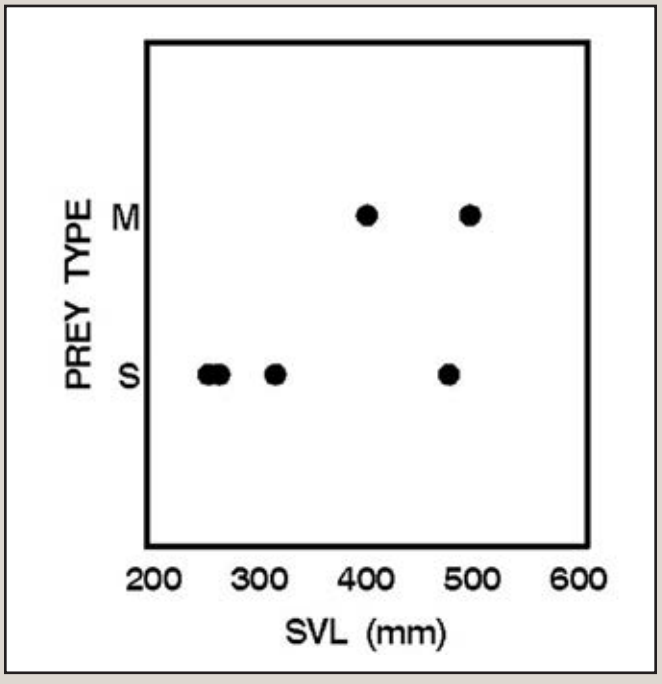

FIG. 3. Plot of prey type (S = snake; M = small mammal) against snout–vent length (SVL) for six Milksnakes (*Lampropeltis triangulum*). All snake prey were *Storeria dekayi* and all mammal prey were nestling or juvenile rodents. One Milksnake (400 mm SVL) shown on this plot had three nestling rodents in its gut, but all others had just one prey item; a seventh Milksnake (249 mm SVL), not shown in this plot, had an unidentified prey in its gut.

FIG. 4. Photograph of a Milksnake (*Lampropeltis triangulum*, bottom) alongside prey (DeKay's Brownsnake, *Storeria dekayi*, top) that it regurgitated upon capture. The Milksnake had a snout–vent length (SVL) of 261 mm and weighed 6 g; the Brownsnake measured approximately 200 mm SVL and weighed 4 g.

males reach slightly greater lengths than females (Fitch and Fleet 1970; Fitch 1999; Hamilton et al. 2012), although, where tested, this difference is statistically non-significant (Rodríguez and Drummond 2000). This pattern differs strongly from that seen in other snakes, in which sexual dimorphism in size and relative mass is strongly evident, and change in mass with respect to SVL is allometric (e.g., Gregory 2004b).

Dyrkacz (1977) noted that most of the Milksnakes that he collected in Illinois were found under cover. According to Fitch and Fleet (1970), Milksnakes do not usually bask in the open, but are thigmothermic, relying on the underside of sun-exposed cover objects, especially flat rocks, as a source of heat. Thus, the high rate of cover use by snakes at my study site is no surprise. Could such cryptic behavior explain why Milksnakes are relatively scarce and understudied? Perhaps, but the other species of snakes at my study site, including three very common ones, also are mostly found under rocks (Gregory 2004a; Gregory and Tuttle, *in press*). Milksnakes are nocturnal in parts of their range (Hamilton et al. 2012), which also would make them inconspicuous, but the extent of nocturnality in northern populations is unknown. Finally, weather also might influence diurnal cover use, but I did not record pertinent data to test this.

The tendency of larger Milksnakes to be in the open is in line with observations of several other species of snakes (Gregory 1984; Mertens 1995), including others at the same study site (Gregory and Tuttle, *in press*). Presumably, this reflects the lower risk of predation that large adults face in the open compared to small snakes. Benefits of being in the open include basking opportunities for thermoregulation (i.e., adults might be partly heliothermic and not just thigmothermic). Thermal quality is an important driver of micro- and macrohabitat selection in northern populations of *L. triangulum* (Row and Blouin-Demers 2006b).

Injuries were rare in my sample of Milksnakes, perhaps reflecting the overall high use of cover, but it is noteworthy that the two injured animals I found were the largest individuals. Larger (presumably older) snakes are more likely to have injuries for at least two reasons: a) small snakes that are attacked by a predator are more likely to be killed outright than to survive with an injury; and b) older snakes simply have had more time to acquire injuries (Gregory and Isaac 2005).

Milksnakes have been reported to eat a diversity of prey, but mainly small mammals (shrews and rodents), squamate reptiles (mainly lizards, but also snakes and their eggs), and nestling birds (Fitch and Fleet 1970; Dyrkacz 1977; Brown 1979; Fitch 1999; Navarrete and Rodríguez-Acosta 2003; Ellison and Ribic 2012; Hamilton et al. 2012). Mammals are generally more important prey than birds, but there are exceptions (Rodríguez and Drummond 2000). Thus, broadly speaking, the diet of Milksnakes at my study site appears to be typical of the species. My data are also consistent with published evidence for an ontogenetic shift in diet from ectotherms (squamates) in small Milksnakes to endotherms (mammals or birds) in larger snakes (Fitch and Fleet 1970; Fitch 1999; Rodríguez and Drummond 2000; Hamilton et al. 2012). Fitch (1999) found that only adult snakes ate mammals, whereas smaller Milksnakes ate only reptiles, suggesting an abrupt ontogenetic change in diet. However, other data suggest a more gradual transition, with mammal prey being added to a diet of squamates before becoming virtually the only prey of the largest snakes (Hamilton et al. 2012). My data, scant as they are, indicate a gradual shift in diet (Fig. 3). Hamilton et al. (2012) found a geographic trend in Milksnake diets, with a higher proportion of mammal prey at higher latitudes; a larger sample, especially of large snakes, would be needed to determine whether this is the case at my study site.

In captivity, hatchling Milksnakes readily eat small neonate mice (pers. obs.), but, given the high growth rate of nestling rodents, such young and small prey may be difficult to find in the wild; they also may be difficult for small snakes to consume if mammal nests are attended by deterrent mothers. Fitch and Fleet (1970) argued that Milksnakes, with their slender bodies and "small and delicate" head and jaws, are not adapted for eating bulky prey. Thus, prey with small cross-sections, such as small snakes, should be more likely to be within the gape limits of small Milksnakes and therefore more easily eaten. However, because they may be long, snakes can nonetheless be bulky prey and consuming them presents its own challenges (Jackson et al. 2004). My observation that the *Storeria* inside the Milksnake shown in Fig. 4 was folded along its vertebral axis is consistent with observations of how Common Kingsnakes (*Lampropeltis getula*) swallow large snake prey (Jackson et al. 2004).

Only one species of lizard occurs in southern Ontario and it is absent from my study area, so available squamate prey for Milksnakes is limited to snakes. *Storeria dekayi* is a commonly encountered species at my study site, is small even when adult, and is mainly found under rocks, so it may be easy and abundant prey for *Lampropeltis*. However, two other species of small snakes occur in much smaller numbers at the study site and both are known prey of Milksnakes: *Storeria occipitomacula* (Brown 1979) and *Diadophis punctatus* (Fitch and Fleet 1970; Fitch 1999). Furthermore, the young of two larger and abundant species, *Thamnophis sirtalis* and *Nerodia sipedon*, presumably would be available to Milksnakes. Thus, there are multiple snake species on which young *Lampropeltis* could feed. Whether my sample is biased because it is small or *Lampropeltis* actively selects *S. dekayi* remains to be determined. Gray (2014a, 2015) also recorded juvenile Milksnakes preying on Brownsnakes in Pennsylvania; he noted that Milksnakes at that site did not eat *T. sirtalis*, but provided no evidence (Gray 2015).

In a laboratory setting, neonate *Thamnophis elegans* avoid shelters bearing the odors of adult conspecifics, which are sometimes ophiophagous and even cannibalistic (Waye and Gregory 1993). Similarly, if small Milksnakes at my study site specialize on Brownsnakes, then we would expect the latter to avoid the former. This is supported by observations that Milksnakes are sometimes found under rocks with other

snake species (*Diadophis*, *Thamnophis*), but not Brownsnakes (Gregory 2004a). However, Gray (2014b) noted that Milksnakes in Pennsylvania are often found under cover with Brownsnakes. Again, my sample is small and this question would benefit from careful experimental work.

Acknowledgments.—I thank Dan Gregory for providing accommodation while doing fieldwork in Oakville. Tom Gore took the photograph in Fig. 4. Linda Gregory and three reviewers made useful comments on the manuscript. This work was done under permit from the Ontario Ministry of Natural Resources and with the signed approval of the University of Victoria Animal Care Committee. Financial support was provided by a Discovery Grant from the Natural Sciences and Engineering Research Council of Canada.

The Identity of a Controversial Neotropical Turtle Hatchling (Reptilia: Testudines: Chelidae)

Due to lack of data and available specimens with confirmed genealogy, the identification of hatchling South American chelid turtles has been difficult and controversial through time. Neonates of few species are unmistakable, either by body profile (*Chelus fimbriata*, *Platemys platycephala*, *Hydromedusa* spp.) or by persistence through life of the ground color or pattern that adults exhibit (e.g., *Phrynops hilarii*). In many other species, however, the hatchlings show coloration and/or patterns that shift across ontogeny, e.g., *Mesoclemmys dahli* (Rueda-Almonacid et al. 2007), *M. gibba* (Métrailler 2001; Rueda-Almonacid et al. 2007; Vogt 2008), *M. tuberculata* (Santana et al. 2015), *M. zuliae* (Pritchard and Trebbau 1984; Rueda-Almonacid et al. 2007), *Phrynops geoffroanus* (Pritchard 1979; Pritchard and Trebbau 1984), and *Phrynops tuberosus* (Böhm 2008; Coelho et al. 2014). Identifying empty shells of juvenile turtles is even harder, due to the occurrence of a yellowish plastron with central expanded black area in several species, e.g., *Mesoclemmys gibba* (Métrailler 2001), *M. heliostemma* (Rueda-Almonacid et al. 2007), *M. nasuta* (Métrailler and Le Gratiet 1996), *M. raniceps* (Böhm 2009), *M. tuberculata* (Reis et al. 2014), and *M. vanderhaegei* (Marques et al. 2014).

The purpose of this paper is to set the identity of a hatchling chelid turtle, purportedly the southernmost record of *Mesoclemmys vanderhaegei* (Bour) (Iverson 1986, 1992), whose identification has been doubted repeatedly (Waller and Chebez 1987; Cabrera 1998; Vinke et al. 2013). This specimen is housed at the Zoologisches Museum Hamburg as ZMH R 1025 (Fig. 1A). Associated data to it are: "*Phrynops nasutus* aus Puerto Malabrigo, Paraná, Provinz Santa Fé, östlicher Rand des südlichen Chaco, Argentinien, von Dr. Med. Schreiber, 5.4.1930."

Puerto Malabrigo is a domestic harbor (not to be confused with the city of Malabrigo, located about 38 km to northwest of it) on the western bank of the Paraná River, at 29°2957S, 59°3701W. The locality is situated about 520 km from the nearest record of *Mesoclemmys vanderhaegei* (Arroyo Zaimán at Misiones Province; Cabrera 1998), assuming dispersal via the Paraná River, or about 380 km from the nearest northern record, if dispersal was via the Paraguay River (Laishí, Formosa Province; Cabrera 1998).

Upon close inspection of ZMH R 1025, we determine that the specimen is a hatchling of the Chaco Side-necked Turtle *Acanthochelys pallidipectoris* (Freiberg). This species has been cited from Santa Fe province (Fernández 1987; Buskirk 1988; Cabrera 1998; Piña and Larriera 2001; Vinke et al. 2011) but it is rarely encountered and vulnerable for being endemic to the Chaco ecoregion. Our determination of the true identity of this hatchling is supported by the following evidence.

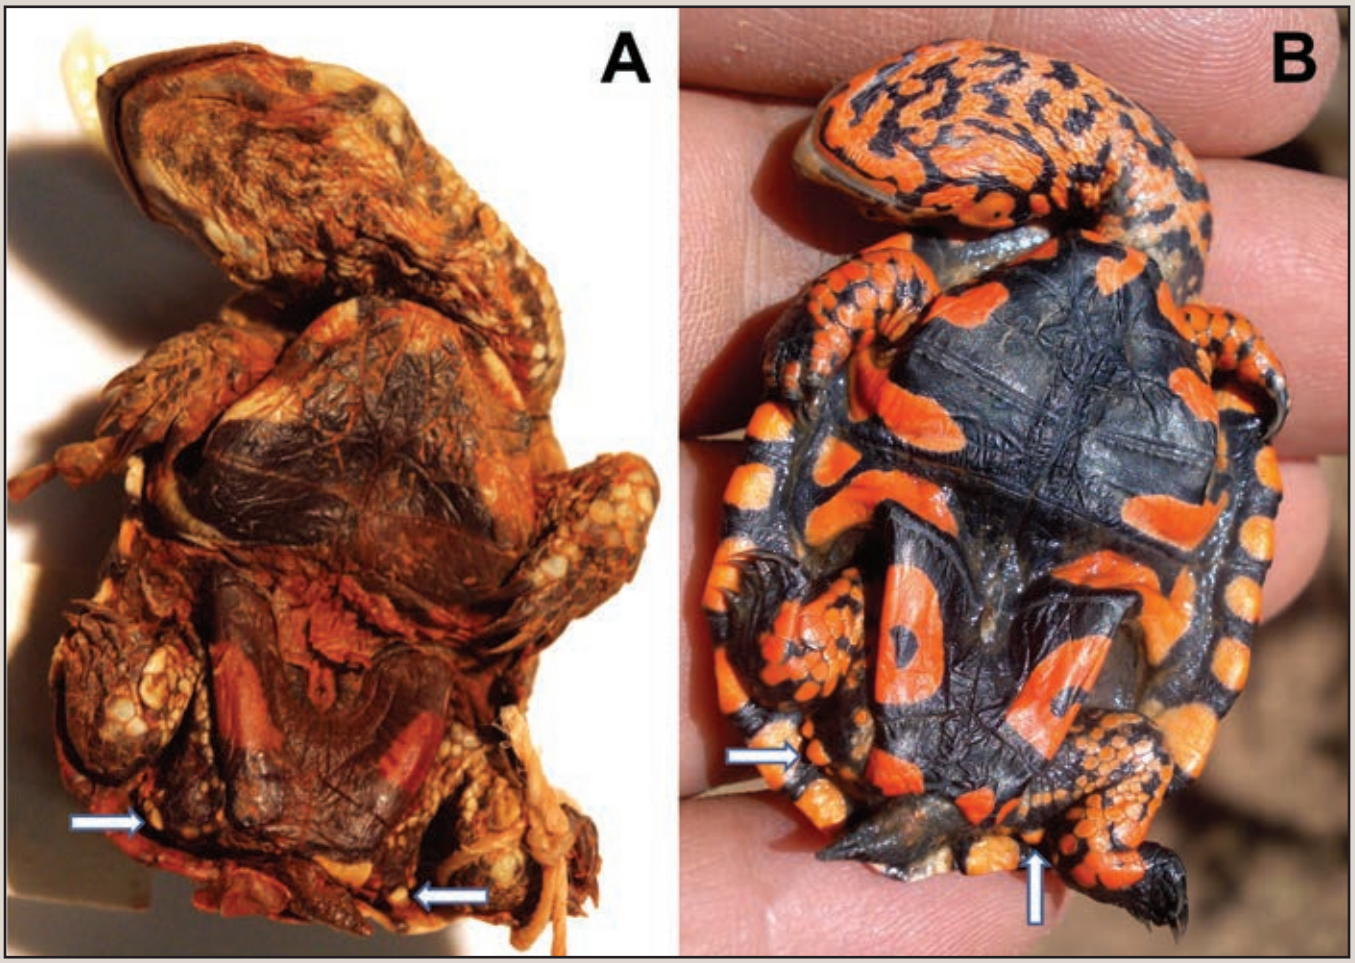
Morphology.— (a) Although considerably smaller than in adults, ZMH R 1025 (Fig. 1A) bears the femoral spurs that only *A. pallidipectoris* exhibits. (b) The noticeable narrowing at the sides of the carapace is due to the freshly-hatched condition of this individual.



Size.—This specimen's straight-line carapace length (SCL) = 28.4 mm; in three specimens of *A. pallidipectoris* bred in captivity the shell of hatchlings had an average length of 31 mm (Vinke et al. 2011). On the contrary, *Mesoclemmys* hatchlings are at least 35 mm SCL when they hatch, according to our observations on captive-born *M. gibba* and *M. raniceps* (Böhm 2009, and unpublished data). Santana et al. (2015) reported a carapace length of 47.1 mm for *M. tuberculata* , and Souza et al. (2000), in the only published reference to hatchling size of *Mesoclemmys vanderhaegei*, reported SCLs of 39.2 mm and 41.9 mm for two wild-hatched neonates.

Pattern and color.—There is full concordance of the ZMH R 1025 hatchling with living *A. pallidipectoris* juveniles (Fig. 1B). For comparison with *M. vanderhaegei*, see figure 5 in Marques et al. (2014) that shows the largely black plastron and soft body parts of a live *M. vanderhaegei* hatchling.

From an ecological perspective, passive transport of a tiny *M. vanderhaegei* (or any other chelid hatchling) by drifting in a large river through hundreds of kilometers seems unlikely due to hazardous presence of abundant predatory fishes such as *Hoplias malabaricus*, *Salminus brasiliensis,* and others, as well as crocodilians (*Caiman latirostris*, *C. yacare*), in both the Paraná and Paraguay rivers (Vinke et al. 2013). All the species of the genus *Acanthochelys* (*A. macrocephala*, *A. pallidipectoris*, *A. radiolata*, and *A. spixii*) have small hatchlings with vivid red, orange, or yellow colors present on the marginal scutes, the plastron, and soft body parts (Cabrera 1998; Artner 2007; Mocelin et al. 2008; Vinke et al. 2011). Upon growing, these colors fade or disappear altogether, being replaced by brown or black. These bright colors might act as aposematic signals to discourage potential predators of these vulnerable animals in the early stages of their lives. For example, experiments by Britson (1998) and Britson and Gutzke (1993) showed that Largemouth Bass might associate the bright plastral colors and patterns of Red-eared Sliders (*Trachemys scripta*) with the defensive behavior of the turtle. However, in sediment-rich rivers with turbid water such as the Paraná, protection by color cannot act.

The clarification of the true identity of the ZMH R 1025 specimen allows better definition of the actual range of *M. vanderhaegei*, a species assessed as IUCN Data Deficient or Near Threatened (Marques et al. 2014). Except for reference to this hatchling, *Mesoclemmys vanderhaegei* never has been found farther south than 28ºS latitude. This chelid turtle is therefore limited to Brazil, Paraguay, and small portions of southeastern Bolivia and northeastern Argentina.

Acknowledgments.—We thank Jakob Hallermann (Zoologisches Museum Hamburg, Germany) and Georg Gassner (Naturhistorisches Museum Vienna, Switzerland) for logistical assistance. Soledad Palomas authorized us to use her live hatchling photograph. Associate

A Synthesis of Direct Evidence of Predation on Amphibians in New Zealand, in the Context of Global Invasion Biology

There are currently almost as many threatened amphibian species as there are threatened mammalian and avian species combined (Bishop et al. 2012; IUCN 2014). Although the decline of amphibians has been of international concern for more than two decades, the direct causes of these declines are often difficult to identify, or they are difficult to disentangle as they may be acting synergistically (Alford and Richards 1999; Alford et al. 2001; Stuart et al. 2004). Introduced fauna are ranked as the third most important detrimental factor affecting amphibians after habitat modification and pollution (Chanson et al. 2008). Amphibians that have little or no evolutionary history with introduced fauna can exhibit naive responses that are not well suited for survival (Diamond and Case 1986; Gillespie 2001; Kats and Ferrer 2003) and the effect of introduced predators is predicted to be most acute in island ecosystems (Schoener and Spiller 1996; Courchamp et al. 2003; Ahola et al. 2006), particularly on insular endemic species (Diamond and Veitch 1981).

New Zealand's biota evolved in the absence of terrestrial mammals (apart from bats; see Clout and Saunders 1995). The Pacific Rat (*Rattus exulans*) and Polynesian Dog (*Canis familiaris*) arrived in association with the first human settlers in the thirteenth century AD (Anderson and Clark 2001; Wilmshurst and Higham 2004; Wilmshurst et al. 2008) and a range of mammalian species were later introduced by European settlers (from the eighteenth century AD onwards) with 31 introduced mammalian species now present in wild or feral populations (Parkes and Murphy 2003; King 2005).

The native amphibian fauna of New Zealand consists of four extant endemic frog species: Archey's Frog (*Leiopelma archeyi*), Hochstetter's Frog (*Leiopelma hochstetteri*), Maud Island Frog (*Leiopelma pakeka*), and Hamilton's Frog (*Leiopelma hamiltoni*); as well as three species introduced from Australia: Brown Tree Frog (*Litoria ewingii*), Southern Bell Frog (*Litoria raniformis*), and Green and Golden Bell Frog (*Litoria aurea*) (Bell 1994; Newman 1996; Frost et al. 2006). All four native species are ranked within the top 60 most Evolutionarily Distinct and Globally Endangered amphibians in the world, with Archey's Frog topping that list (EDGE 2008). Additionally, the two introduced bell frog species are declining in their native ranges in Australia and are listed as "Endangered" and "Vulnerable" (IUCN 2014).

The current native frog recovery plan considers the primary threats to be predation by rats and other introduced mammals, habitat loss and modification, disease, toxins, herbicides, and climate change (Bishop et al. 2013). While all these threats undoubtedly had, and continue to have, a devastating impact on native frogs, the problem of introduced mammals appears to be one of the most clear cut to remedy, i.e., through the control of mammal populations. Mammal control demands a large amount of resources and is only a viable option if conservation targets, e.g., an increase in frog abundance, are likely to be met. The evidence to date of introduced fauna negatively impacting *Leiopelma*, although convincing, is largely circumstantial. Therefore, the main objective of our study was to re-examine

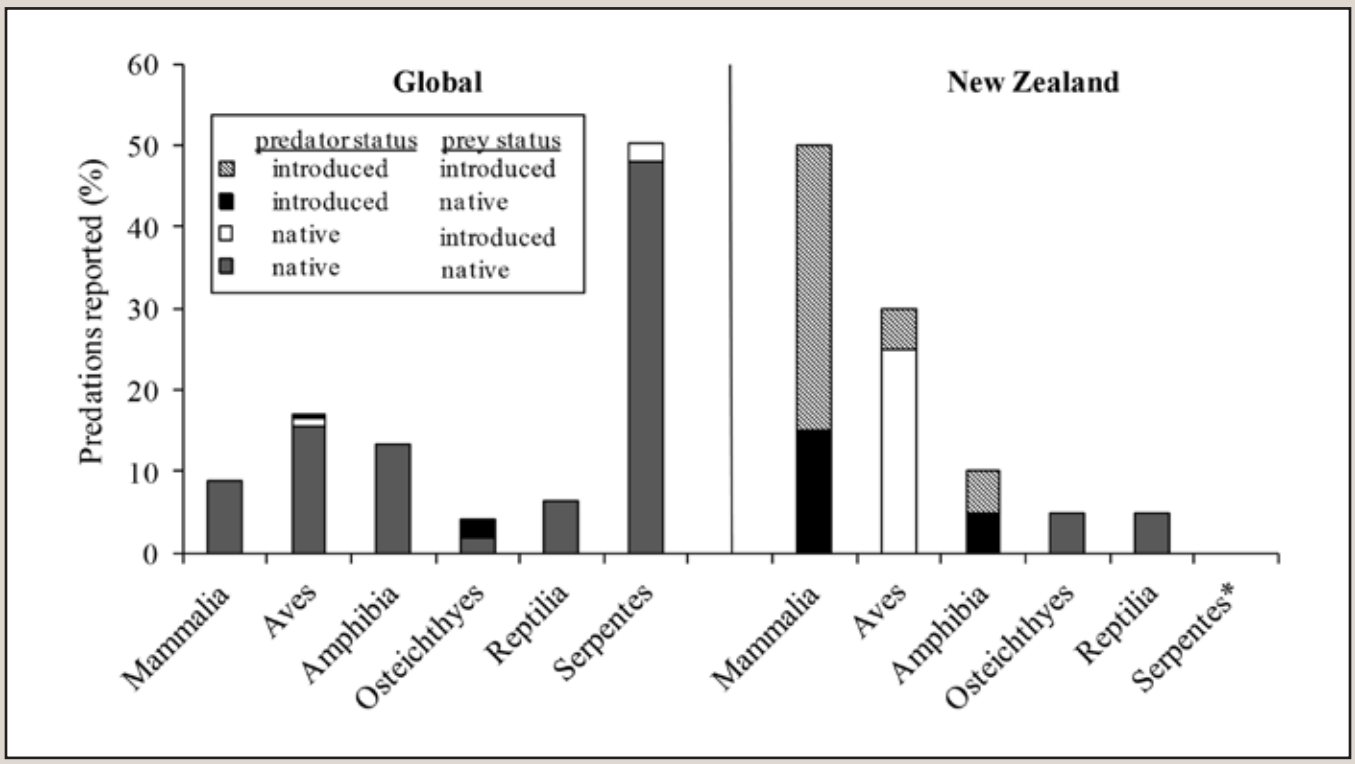

FIG. 1 Reported predator-prey interactions (%) for major vertebrate groups as predators of adult frogs, and their respective status as native or introduced. Global data (N = 217) is from Toledo et al. (2007), New Zealand data is from Table 1 (N = 20). *Note that the group Serpentes is not represented in New Zealand.

the potential for introduced mammals to act as agents of frog declines in New Zealand, using only direct evidence of predation.

The most notable circumstantial evidence for introduced fauna negatively impacting *Leiopelma* comes from the fact that the extinction of three *Leiopelma* species and the range contraction of the currently extant species occurred synchronously with the arrival of introduced mammals, e.g., the Pacific Rat (reviewed by Worthy 1987; Towns and Daugherty 1994). Furthermore, the only known naturally existing populations of the Maud Island Frog and Hamilton's Frog are restricted to mammal-free islands (Bishop et al. 2013).

Although predation by introduced fauna is often referred to in the scientific literature as playing a major role in the current decline of native New Zealand frogs (Worthy 1987; Bell 1994; Bell and Bell 1994; Daugherty et al. 1994; Towns and Daugherty 1994; Holyoake et al. 2001; Bell et al. 2004; Tocher and Pledger 2005; Baber et al. 2006; Haigh et al. 2007; Bell 2010; Bishop et al. 2013), there have so far only been sporadic reports of predation events and there are no published studies quantifying direct evidence of predation (e.g., confirmed predation events). Indirect predation studies have been carried out comparing frog abundance in areas where mammalian predators have been removed against those where no predator control was implemented, but the results to date have been varied.

In a study focused on Archey's Frogs, the Department of Conservation (DOC) ran a large-scale predator removal experiment (from 2005 to 2011). Four frog population monitoring grids were set up, two in an area poisoned for rodents and two in a non-treatment area (Pledger 2011). Over that period frog population sizes remained stable or increased on grids inside the treatment area and decreased in the non-treatment area (Pledger 2011). However, it is not clear whether the data from the relatively small grids (10 x 10 m) can be viewed as representative of the larger 600-ha area.

In a mammal controlled fenced sanctuary (Zealandia, Wellington, New Zealand), a small population of Maud Island Frogs (N = 58) were divided into two groups, with one group placed in a mouse (*Mus musculus*)-proof sub-enclosure and the second released in an area inhabited by mice (Lukis 2009). After one year, only one frog could be found outside the sub-enclosure, while 27 were recaptured inside the sub-enclosure (Lukis 2009). Since then, some more survivors and progeny have been found outside the sub-enclosure, but the population has struggled to survive (B. D. Bell, unpubl. data). However, other potential native avian predators (e.g., Little Spotted Kiwi *Apteryx owenii*, Morepork *Ninox novaeseelandiae*) are also present outside the sub-enclosure, so mice may not have been the only cause of this population struggle.

Nájera-Hillman et al. (2009c) found no difference in the relative abundance of Hochstetter's Frogs between areas that had no rodent control and those that had very low rodent numbers. Conversely, Mussett (2005) and Baber et al. (2008) found that Hochstetter's Frog abundance was far higher in mammal-controlled areas than in non-controlled areas. However, the results of Mussett (2005) were complicated by the fact that at some mammal control sites Ship Rat (*Rattus rattus*) abundance was similar to that of non-control sites. Also, among mammal control sites, the highest Ship Rat abundance coincided with the highest frog abundance (Mussett 2005). It should be noted that only Nájera-Hillman et al. (2009c) considered habitat characteristics in their comparisons, which are known to heavily influence Hochstetter's Frog abundance (Nájera-Hillman et al. 2009b; Nájera-Hillman et al. 2009c). Finally, Nájera-Hillman et al. (2009a) investigated the trophic position of Hochstetter's

TABLE 1. Collation of all reported predation events with frogs as prey in New Zealand. For species names, references, and further details see Appendix 1.

Prey species	Predator species	Predator class	No. of predation events reported
Leiopelma (native to New Zealand)			
Archey's Frog	Ship Rat	Mammalia	19
	Green and Golden Bell Frog	Amphibia	1
Hochstetter's Frog	Ship Rat	Mammalia	2
	Stoat	Mammalia	3
	Banded Kokopu	Osteichthyes	1
Hamilton's Frog	Tuatara	Reptilia	1
Hamilton's Frog or Maud Island Frog†	Laughing Owl, extinct§	Aves	8
Litoria (introduced to New Zealand)			
Green and Golden Bell Frog	Brown Kiwi	Aves	4
	Weka	Aves	4+

† Not distinguished as separate species at the time of the study. * Not identified to species level. § Included here for the sake of completion, but not included in the data set discussed in the text or used to generate Fig. 1. + In cases where the exact number of predation events reported was unclear, only those that could be confirmed were used.

Frog using stable isotope analysis and concluded that Short-finned Eels (*Anguilla australis*) and Banded Kokopu (*Galaxias fasciatus*) might be more significant potential predators than Ship Rats. However, the results for the trophic position of Ship Rats in relation to frogs were inconclusive (Nájera-Hillman et al. 2009a).

Given these varied results, we aimed to clarify the potential for various predator groups to act as agents of frog declines in New Zealand. To do this, we collated all known reports of direct evidence of predation on frogs in New Zealand, providing conservationists with a comprehensive and up-to-date catalogue of known frog predators. We define "direct evidence" as either observations of predation events or prey remains of frogs found in predator stomach and fecal contents. Based on these data, we aimed to identify 1) predator groups that have most been reported as predators of frogs in New Zealand, and 2) predator groups for which predation data is scarce and require further research. Furthermore, we intended to compare the data with global trends, in terms of 1) the percentage of predator-prey interactions attributed to each major predator group, and 2) the percentage of predator-prey interactions attributed to introduced predator species.

We collated all known reports of predation events involving frogs as prey in New Zealand (Table 1; and see Appendix 1). In order to place the data in a global context, we compared it to a similar, but globally inclusive, review carried out by Toledo et al. (2007). Using the information (predator species, prey species, and cited reference) from Toledo et al. (2007), along with the known global distribution of the predator and prey in each case (IUCN 2014), we determined the proportion of reports involving introduced fauna.

It should be noted that we did not include the following predation events listed in Toledo et al. (2007): reports based on frogs being presented to potential predators during laboratory feeding trials (N = 18); reports where locations were not provided (N = 4); reports from New Zealand (N = 3); and reports that appeared to be erroneous (N = 1; the original reference [Caudell et al. 2000] reported a Cane Toad [*Rhinella marina*] consuming a Brown Tree Snake [*Boiga irregularis*], rather than vice versa). Data pertaining to predation events in New Zealand were obtained

using the following search terms in varying combinations: frog, diet, New Zealand, prey, predation, predator, stomach, faecal, contents, *Leiopelma*, and *Litoria*. Databases searched include Google Scholar, the New Zealand Department of Conservation (DOC) publications (http://www.doc.govt.nz/publications/), and the University of Otago library database collection (which includes BioOne, Web of Science Core Collection, Web of Science Zoological Record, Scopus, Science Direct, ProQuest Biological Science Collection and Index New Zealand). Furthermore, we contacted DOC to request any information not publicly accessible. Relevant citations within accessed material were also specifically searched for and included. In total, we collated data from at least 119 predation events in New Zealand, involving 17 predator species, at least 6 frog species and 21 predator-prey interactions (Table 1).

The major difference between predator-prey interactions involving frogs as prey in New Zealand, compared to the global reports reviewed by Toledo et al. (2007), is the proportion attributed to introduced fauna (65% for New Zealand, 2.8% for global data; Fig. 1). A much higher proportion of predator-prey interactions also involved introduced frogs as prey in New Zealand (70%) compared to the rest of the world (3.2%), but this might be expected as there are almost as many introduced frog species in this country as there are native. Given that Serpentes are not represented in New Zealand, the general trend appears to be partially similar to that for the rest of the world, with Aves being a highly reported predator group, followed by Amphibia, Osteichthyes, and Reptilia (Fig. 1). However, the proportion of predator-prey interactions attributed to mammals is far greater in New Zealand (50%) than for the rest of the world (8.8%; Fig. 1). Viewing the data for New Zealand in terms of predation events reported, rather than predator-prey interactions, yielded similar results, the vast majority of events being attributed to mammals (73%; see Table 1).

Based on all known reports, it seems that introduced small mammal species, particularly rodents, may represent the greatest threat to New Zealand's frogs. Furthermore, Ship Rats, Norway Rats (*Rattus norvegicus*), and Pacific Rats have reached about 90% of the world's islands and are likely to pose a major threat to native amphibians in many countries (Innes 2005; Towns et al. 2006).

Our study also shows the apparent paucity of data pertaining to direct evidence of predation on native New Zealand frogs–there have only been five predator species reported, three of which are introduced. Some major predator-prey interactions have **not** been reported in New Zealand, including: Aves as predators of native frogs; introduced Osteichthyes as predators of native frogs; Osteichthyes as predators of introduced frogs and; Reptilia as predators of introduced frogs. Given the global data (Toledo et al. 2007), it would be surprising if these interactions were not taking place and it is likely they have just not yet been observed or reported.

The majority of the predation events collated in the present study were not directly observed, but based on prey remains from predator stomach contents. This is standard practice in ecology (Hyslop 1980; Corse et al. 2010). However, the successful identification of prey depends on an array of factors and can be undertaken using a variety of techniques that can yield very different results. For example, DNA-based diet analysis has been shown, under laboratory conditions, to increase the prey detection rate of frogs in small mammal stomach contents from 2% to 70% (Egeter et al. 2015). It is important to note that the global reports referred to in the present study were limited to those where prey had been identified to species level (Toledo et al. 2007) and this may have caused a bias against the inclusion of mammalian predators. Furthermore, the review was largely limited to reports published in *Herpetological Review* (Toledo et al. 2007), and as such may have included a higher proportion of reports of the prey of herpetofauna than that of other taxa. On the contrary, due to the fact that conservation practices in New Zealand often focus on the effects of introduced mammals, our collated data may have included a bias toward their inclusion. However, as our study aimed only to include information from direct, non-circumstantial, predation events, these caveats are not considered to be major constraints on the data, rather the data help to indicate predator groups for which we have information, as well as predator groups where information is scarce and require further research in order to be properly assessed as potential agents of frog decline.

Based on the results of this synthesis, further research is needed on the impacts of birds, fish, and reptiles on native frogs in New Zealand if we are to build a more complete picture of the predation threats they face. With regard to introduced mammalian predators, only four of the ten species known to consume vertebrates have **not** been reported as predators of frogs: weasels (*Mustela nivalis vulgar*), Norway Rats, House Mice, and possums (*Trichosurus vulpecula*). We therefore suggest that introduced mammals can be considered as having a substantial negative impact on frogs in New Zealand, but that other, perhaps understudied, introduced fauna may also be having an effect.

This study provides the first synthesis of all the known predators of frogs in New Zealand, a valuable resource for frog conservationists, and this information will enable researchers and managers to make better-informed decisions when focussing on predation on frogs in New Zealand. It also draws attention to the paucity of information on the effects of biological invasions on amphibians and has revealed the prevalence of predation on Southern Bell Frogs and Green and Golden Bell Frogs, both of which are threatened and declining in their native ranges in Australia (IUCN 2014), where Feral Cats (*Felis catus*), Ship Rats, Norway Rats, and House Mice have been introduced. Although introduced fish, particularly Mosquito Fish (*Gambusia holbrooki*), are known to have a detrimental effect on bell frog populations in Australia (Pyke and White 1997), very little research has been carried out on the impacts of terrestrial predators.

There have been many studies showing a negative correlation between the introduction of novel predators and native amphibian populations (e.g., Bucciarelli et al. 2014; reviewed by Kats and Ferrer 2003). Fish appear to be the most geographically widespread of the introduced predator groups affecting amphibians (Stebbins and Cohen 1997; Kats and Ferrer 2003). Our re-examination of the data collated by Toledo et al. (2007) concurs with this as 55.6% of the reported Osteichthyes-amphibian interactions could be attributed to introduced Osteichthyes predators.

New Zealand's frogs face a host of threats and a combination of strategies are required to ensure their survival, such as translocations to suitable habitat, habitat enhancement (e.g., through the use of predator control), disease monitoring, and policy implementation to reduce toxins and herbicides in the environment. We are only at the beginning of our journey to counter global amphibian declines, especially in terms of the effects of introduced fauna. The application of novel techniques

to detect predation, as well as the collation of existing knowledge, will help conservationists to discern and combat the detrimental effects of introduced fauna. It is only once more data becomes available on native frogs around the world, as well as on their predators, that the case for effective predator control can be made, resulting in a decrease of the impacts of introduced fauna and the conservation of the world's rich and diverse amphibian biota.

Acknowledgments.—We thank the New Zealand Department of Conservation for contributing data to this paper. Funding was provided by the University of Otago, Dunedin, New Zealand. The authors declare that they have no conflict of interest and have complied with applicable institutional animal care guidelines.

Appendix 1

Collation of all reported predation events with frogs as prey in New Zealand.

Prey species	Predator Species	Additional Information	References
Archey's Frog (*Leiopelma archeyi*)	Ship Rat (*Rattus rattus*)	12 dead frogs with Ship Rat bite marks evident, plus an additional 5 dead frogs with Ship Rats as suspected cause of death. *L. archeyi* DNA identified from 2 stomachs (out of 17).	Thurley and Bell (1994), Fitzgerald and Campbell (2002), O. Overdyck (pers. comm.), Egeter (2014)
	Green and Golden Bell Frog (*Litorea aurea*)	1 Green and Golden Bell Frog stomach inspected and found to contain an Archey's Frog.	Thurley and Bell (1994)
Hochstetter's Frog (*Leiopelma hochstetteri*)	Ship Rat	1 dead frog with Ship Rat bite marks evident. *L. hochstetteri* DNA identified in 1 stomach (out of 117).	Fitzgerald and Campbell (2002), Egeter (2014)
	Stoat (*Mustela erminea*)	1 Stoat observed carrying live frog, 2 further dead frogs with likely Stoat bite marks evident.	Baber et al. (2008)
	Banded Kokopu (*Galaxias fasciatus*)	1 ingested frog found (out of 369 stomachs).	West et al. (2005)
Hamilton's Frog (*Leiopelma hamiltoni*)	Tuatara (*Sphenodon punctatus*)	1 frog hind limb found in Tuatara feces (out of 14 fecal samples).	Newman (1977)
Hamilton's Frog or Maud Island Frog (*Leiopelma pakeka*)	Laughing Owl (*Sceloglaux albifacies*), extinct	Fossil deposit of prey collected; minimum of 8 individual frogs (out of 79 total prey individuals). Not distinguished as separate species at the time of the study.	Worthy and Holdaway (1994)
Green and Golden Bell Frog	Brown Kiwi (*Apteryx australis*)	Identified in Kiwi feces in an area with a high abundance of frogs, yet the incidence in scats was very low.	Kleinpaste (1990)
	Weka (*Gallirallus australis*)	Frog remains in gizzards (frequency of occurrence 4.7% and 2.9% in respective studies).	Carroll (1963), Coleman et al. (1983)
	Australasian Harrier (*Circus approximans*)	Minimum of 6 frogs out of 243 total prey. Also observed taking frogs by B. D. Bell.	Baker-Gabb (1981), Newman (1982)
	Feral Pig (*Sus scrofa*)	1 frog (out of 50 stomachs).	Krull and Egeter (2016)
Brown Tree Frog (*Litoria ewingii*)	Cat (*Felis catus*)	5 frogs brought to owners' houses (out of 981 prey).	Morgan et al. (2009)
	Ferret (*Mustela putorius furo*)	1 frog out of 12 stomachs.	Clapperton et al. (2011)
	Southern Bell Frog (*Litoria raniformis*)	Both Thurley and Bell (1994) and Mace (2005) cite Bruce W. Thomas, pers. comm., and Littlejohn (1982) mentions unpublished observations, when stating Southern Bell Frogs are known to kill Brown Tree Frogs in the South Island.	Thurley and Bell (1994), Littlejohn (1982), Mace (2005)

Appendix I - Continued

Prey species	Predator Species	Additional Information	References
Southern Bell Frog	European Hedgehog (*Erinaceus europaeus*)	Present in 15% of hedgehog scats collected (and 31% of scats collected in frog breeding areas), 3 hedgehogs observed eating live frogs. One frog found in stomach contents (out of two stomachs).	Brockie (1959), Stewart (2012), Stephen Chadwick (pers. comm.), Egeter (2014)
	Cat	1 frog out of 558 prey items brought to owner's house (all from 1 cat). Cat seen carrying 1 frog.	Flux (2007), Phil Bishop (pers. obs.)
Southern Bell Frog or Brown Tree Frog	Ferret	In ca. 17% of scats, could not be identified to species level.	Roser and Lavers (1976)
	Cat	2 frogs brought to owners' houses (out of 1674 prey), could not be identified to species level.	Gillies and Clout (2003)
	White-faced Heron (*Egretta novaehollandiae*)	Observed herons eating frogs, especially in summer.	Lo (1991), N. M. Grimmond, unpublished data cited by Newman (1982)
	Little Owl (*Athene noctua*)	8 frogs in 2 stomachs (from 242 owls).	Marples (1942)
Southern Bell Frog or Green and Golden Bell Frog	Little Shag (*Microcarbo melanoleucos brevirostris*)	2 out of 56 stomachs. Not distinguished as separate species at the time of the study.	Dickinson (1951)

Time of Night as a Technique for Conducting American Alligator (*Alligator mississippiensis*) Surveys

Nighttime surveys are a common method for monitoring crocodilian populations because there is an established protocol, they are cost effective, and they provide useful information about abundance, distribution, and size composition (Taylor and Neal 1984; Lentic and Connors 2006; Fujisaki et al. 2011). Woodward and Marion (1978), Lutterschmidt and Wasko (2006), and Eversole et al. (2015) found that several environmental parameters (e.g., water parameters, air temperature, wind speed, cloud cover, moonlight, and precipitation) influence detection rates during alligator surveys. Chabreck (1966) suggested that survey route, time of year, and observer experience contribute large amounts of variability to American Alligator (*Alligator mississippiensis*) survey results (Wood et al. 1985). Understanding how these factors contribute to variation in activity enables managers and scientists to predict optimal times for conducting surveys that will lead to higher detection rates and more accurate estimates of population parameters (Brown and Shine 2002). Wood et al. (1985) indicated that although they did not specifically measure its effects, "timing of surveys probably contributed to variation among these indices." Additionally, Bugbee (2008) recommended conducting alligator surveys after midnight and continuing into the early morning hours to maximize counts of adult alligators. Currently in Texas, the state protocol for conducting annual American Alligator surveys requires that survey start times occur at 30 minutes past sunset and that surveys be conducted during July and August (Thompson et al. 1984). However, scientific research has not determined if this survey start time is optimal for American Alligators in Texas or if it is applicable across all age classes of alligators. Although fluctuating environmental variables may explain why alligator detectability varies from survey to survey, such variables typically do not change substantially during a survey-night. Time of night may encompass all or most variables attributing to alligator detectability during a planned survey. A technique of planning surveys around optimal times conducive to maximum alligator detectability may provide an easily utilized protocol for conducting nighttime alligator surveys. Therefore, the objectives of this study were to 1) determine how time of night affects the estimated relative density of American Alligators from nighttime surveys across all alligator age classes, and 2) use this information to evaluate current survey protocol and potentially guide future survey protocol in order to maximize detectability of American Alligators during nighttime surveys.

Methods and Materials

Study Area.—Our study was conducted at Brazos Bend State Park (BBSP) located in Fort Bend County, Texas, USA. The alligator population in the park is considered one of the largest, non-hunted, inland populations of alligators in the state (Texas Parks and Wildlife Department [TPWD], unpubl.) and is surveyed annually as part of the TPWD alligator monitoring and management program. Brazos Bend State Park is comprised of 1982 ha, which includes three lakes that were surveyed for alligators during our study. Survey lakes included Elm Lake, Forty-acre Lake, and Pilant Lake, which were 29.1, 34.2, and 16.3 ha, respectively. Aquatic plant species in these three lakes include Common Water Hyacinth (*Eichhornia crassipes*), Alligator Weed (*Alternanthera philoxeroides*), Coontail (*Ceratophyllum demersum*), smartweed (*Polygonum* sp.), American Lotus (*Nelumbo lutea*), Wild Rice (*Zizania aquatica*), Common Duckweed (*Lemna minor*), cattails (*Typha* sp.), and Chinese Tallow (*Triadica sebifera*).

Fig. 1. Survey route for nighttime alligator surveys on Elm lake, Brazos Bend State Park, Needville, Texas.

Alligator Surveys.—We conducted nighttime surveys along designated transects (Figs. 1–3) in each study lake using the methods outlined by Chabreck (1966), Thompson et al. (1984), and Webb et al. (2006). Surveys for each lake were conducted during four successive nights per month during a twelve-month period (16 August 2012 to 10 July 2013). Total transect length for Elm, Forty-acre, and Pilant lakes were 5.9, 3.0, and 1.4 km, respectively (Figs. 1–3). Transect locations were chosen in order to survey as close to 100% of the lake area as possible without the risk of overlapping transects and subsequent double counting of sighted alligators. In instances when the boat operator had to pass down the same transect twice (i.e., for ease of boat navigation), alligators sighted during the second pass were not counted. Sunset times ranged from 1724 h to 2036 h. It took ~ 6 h to complete all surveys in one night. Surveys in each lake were classified as early (1–3 h after sunset) or late (3.01–6 h after sunset). Lake order was randomly selected each night. We conducted each survey at 6–8 km/h from a 5.5-m air ranger airboat (American Airboat Corporation, http://www.americanairboats.com) and using two spotlights, each with 200,000 candle power. Trained observers were positioned in boat seats that were elevated 1.5 m above the water's surface. We determined total length (TL) of each individual alligator observed by estimating the distance between the eyes and tip of the snout (i.e., it has been found that this length in inches correlates strongly to total length in feet) (Chabreck 1966). Each animal was recorded in one of three respective size-class categories based on TL estimates obtained from eye to tip of snout estimates; hatchlings (≤ 30.5 cm TL), sub-adults (30.6–182.9 cm TL), and adults (≥ 183 cm TL). If observers were unable to estimate total length, individuals were recorded as an unknown size. We calculated alligator density for each study lake as the number of alligators observed divided by the survey area (ha). Although seasonal activity might vary by sex, we did not capture individuals to determine sex; therefore, variability due to sex differences was not included in our analysis.

Statistical Analysis.—To determine differences in alligator relative density in relation to survey start time, we used alligator density (number of alligators/ha) as the dependent variable instead of alligator count data in order to satisfy the assumptions of normality underlying this analysis. We used a mixed model procedure (PROC MIXED; Littell 2006) in SAS (SAS Institute, Inc. 1999) to determine differences in density by survey time, month, and alligator size class, as well as interactions between each of these variables. The mixed model procedure fits a variety of mixed linear models to data in order to make statistical inferences (SAS Institute, Inc. 1999). A mixed linear model is a generalization of standard linear models that are robust to correlation and nonconstant variability (SAS Institute, Inc. 1999). If significant interactions were detected, single variables of the interaction were analyzed separately within each grouping of the other main effects. If the comparison of means showed significant differences ($P \leq 0.05$), we used a test of least significant differences (LSD) to make pair-wise comparisons (SAS Institute, Inc. 1999).

Results

Alligator detectability and hence, the estimated relative density of alligators, was affected by time of night. We detected a significant interaction ($F_{2, 127} = 4.11$, $P = 0.019$) between alligator size and time of survey on alligator density (Table 1). Number of hatchlings observed was unaffected ($F_{1, 127} = 0.48$, $P = 0.488$) by survey time; however, subadult and adult alligators were observed more readily observed ($F_{1, 127} = 17.71$, $P < 0.001$) during later survey times (3–6 h after sunset) than during early

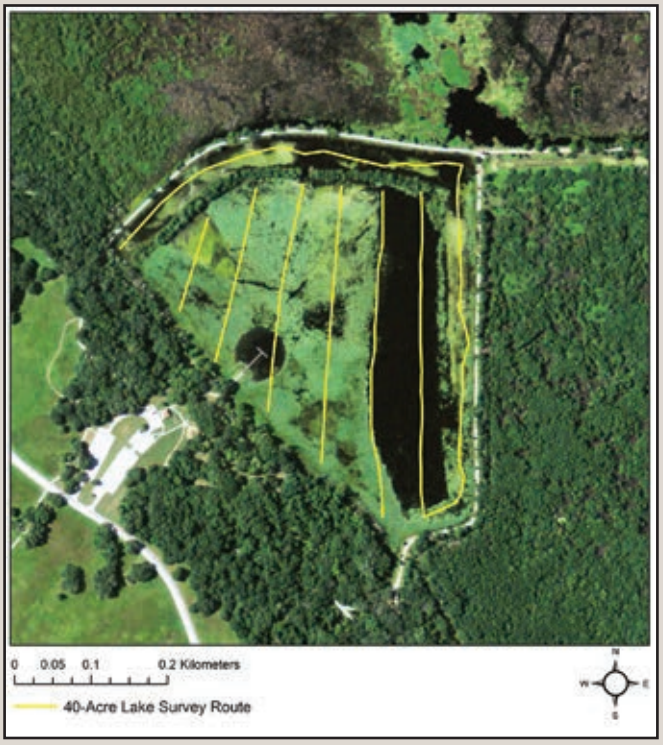

Fig. 2. Survey route for nighttime alligator surveys on Forty-Acre lake, Brazos Bend State Park, Needville, Texas.

Fig. 3. Survey route for nighttime alligator surveys on Pilant lake, Brazos Bend State Park, Needville, Texas.

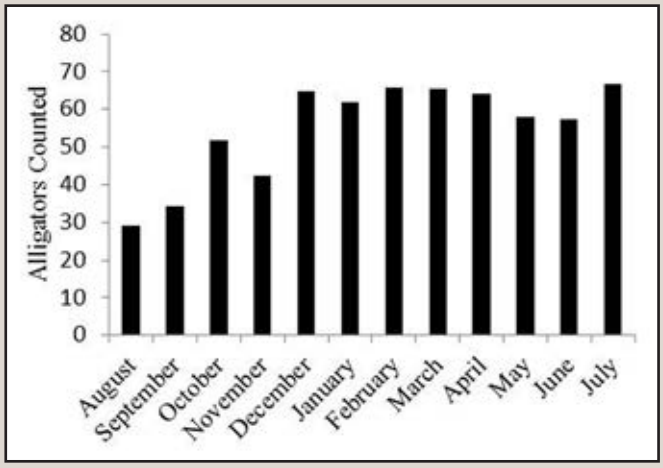

FIG 4. Mean total number of alligators counted during nighttime surveys at Brazos Bend State Park, Needville, Texas, by month.

TABLE 1. Alligator density (alligators/ha ± SE) calculated for three alligator sizes during surveys conducted early (i.e., within 3 h of sunset) and late (3+ h after sunset) from three lakes in Brazos Bend State Park, Texas, 2012–2013. Means with the same upper case letter are not different (P > 0.05) between survey times. Means with the same lower case letter are not different (P > 0.05) between alligator sizes within the same survey time.

Alligator size	Early survey time	Late survey time
Hatchlings	0.051 ± 0.02 Aa	0.056 ± 0.02 Aa
Subadults	0.062 ± 0.02 Aa	0.089 ± 0.02 Ba
Adults	0.062 ± 0.02 Aa	0.089 ± 0.02 Ba

surveys (1 to 3 hours after sunset) (Table 1). We found monthly differences ($F_{11, 124} = 6.85$, $P < 0.001$) in the density of alligators observed across age classes (Fig. 4), but no seasonal pattern emerged. For instance, alligators were more readily observed in January, May, July, August and November, followed by February and March, April, September, and October, then June, and finally December. No other single or interactive effects were found ($F \leq 1.33$, $P \geq 0.360$).

DISCUSSION

Time of night does affect the estimated relative density of American Alligators from nighttime surveys. Our data are directly applicable to providing survey protocol for wildlife agencies in order to increase the accuracy of nighttime American Alligator surveys.

Sub-adult alligators were more abundant, or detectable, during the late survey periods and exhibited similar patterns to those of adult alligators. Bugbee (2008) attributed the increase in adult alligator emergence during later hours of the night to thermoregulatory behavior because adults lose heat at a slower rate throughout the night; therefore, as time progressed, surveys were dominated by adult alligators. This is a logical reason why adult alligators remain active throughout the night. However, this does not explain why adult alligator detectability increased as survey time progressed later into the night. Although this study did not measure the underlying causal factors behind this relationship, other studies indicate that time is correlated to environmental variables as well as thermoregulation, foraging, and activity patterns (Woodward and Marion 1978; Lutterschmidt and Wasko 2006; Bugbee 2008; Eversole et al. 2015).

Similar detection rates of hatchling alligators between survey times are likely because hatchlings were usually found in areas of dense aquatic vegetation and were never observed far from these areas during nighttime surveys (CBE, unpubl. data), presumably as a mechanism of predator avoidance. The detectibility of hatchling alligators was likely not affected by survey time because this behavior never changed throughout the night and was relatively constant across all surveys resulting in similar relative density estimates.

Differences in alligator density by month might reflect differences in behavior during certain times of the year (e.g., breeding season, overwintering; Lutterschmidt and Wasko 2006; Subalusky et al. 2009). Lutterschmidt and Wasko (2006) found that alligators at a Texas site were most abundant during June and September and least abundant during December and January. Our results agree that alligators are least observable during December, but differ in that alligators were most observable during January and July at BBSP. We hypothesize that alligators move in from surrounding wetlands near BBSP and overwinter in the park's lakes (Subalusky et al. 2009). We believe that the large density observed during January is likely the result of this winter immigration. Increased activity during the breeding season in May, and the hatching of young in August, likely increased detection rates, and therefore relative density estimates, at these times (Bugbee 2008).

The monthly results observed in this study are likely the results of changes in detection rates due to changing environmental parameters (Eversole et al. 2015). However, obtaining and utilizing the environmental data as predictors of optimal survey times may not be practical or intuitive. Our study demonstrated that alligator relative densities are correlated with time, thus time should be incorporated into alligator survey methodology in addition to environmental variables. We demonstrated that surveys for adults and subadults should be conducted at later times (e.g., 3–6 h after sunset). By understanding how alligator relative density changes with time we provide a more efficient technique for planning alligator nighttime surveys as an approach to collecting more accurate data on alligator populations. Agency biologists tasked with enumerating alligator populations should incorporate time of night and environmental conditions into the schedule of when to conduct nighttime surveys for alligators.

Importantly, routes should be surveyed with the aid of GPS units and speed should be maintained during surveys to avoid creating potential biases. Approaching alligators to gain "a better look" could potentially be perceived by alligators as threatening, and thus cause their detectability to decrease in subsequent surveys. Although within the scope of this paper, it might be worthwhile to conduct multiple trial surveys prior to enumerating alligators to habituate alligators to the presence of the boat, spotlights, and surveyors.

We suggest that managers and researchers consider our results and conduct alligator surveys at least 3 h after sunset to optimize subadult and adult alligator counts. In addition, we recommend continuing to conduct surveys during July and August under similar weather conditions.

Acknowledgments.—We thank the Houston Livestock Show and Rodeo, the Henry L. Willet Foundation, East Texas Herpetological Society, and the Brazos Bend State Park Volunteer Organization for financial support. This study would not have been possible

without the field contributions of B. A. Eversole and J. L. Ogdee. We also thank the Texas Parks and Wildlife Department as well as staff and volunteers of Brazos Bend State Park for access to our study site and help with fieldwork. This is contribution number 16-111 of the Caesar Kleberg Wildlife Research Institute. This study was approved by the TAMUK Animal Care and Use Committee (Approval #2011-05-16A). We also thank two anonymous reviewers for insight and thoughts used in improving this manuscript for publication.

Art in Herpetology

As space and available material permit, we will occasionally publish examples of historical as well as contemporary herpetological art. We welcome the submission of historical material under the following conditions:

- The work should be copyright-free and be provided as a high-resolution digitized file (consult Herpetological Art and Illustration Coordinator or Editor for specifications).
- Accompanying text should provide information on the subject matter, artist/illustrator, and publication source. Include references as needed to appropriately attribute information from other sources.

Contemporary artists are invited to submit their own work for publication:

- Artist will retain copyright of all submitted material.
- Accompanying text should provide information about technique, media, or other information likely to be of interest, especially to other artists. Other details of interest include the source of illustration subject (e.g., scientific name, geographic origin, etc.) or the work (e.g., book publication, etc.) for which the illustration was produced.
- Artists are welcome to include contact information (e.g., email address, website location), as well as indicating whether original art or prints are available for sale or if the artist is available for commissioned work.

Material may be submitted for review to Jackson Shedd, Herpetological Art and Illustration Coordinator at jackson_shedd@sbcglobal.net.

Modification of the Radio-Transmitter Harness for Tracking Fossorial Anurans

The small size of many anurans requires that telemetry studies use relatively light transmitters with small batteries, which in turn impart relatively short lifespans for the units. This brief longevity means that to track individual anurans for extended periods, transmitters need to be exchanged periodically (Rathbun and Murphey 1996; McAllister et al. 2004). For externally-attached transmitters, this exchange may be fairly straightforward, although it will require the animals to be repeatedly captured and handled. If using surgically-implanted transmitters, the procedure becomes more complicated and the ethics of multiple surgeries needs to be considered.

The Great Basin Spadefoot (*Spea intermontana*) is an anuran that poses challenges for telemetry: they are relatively small, mainly terrestrial, nocturnal, and fossorial. The latter characteristic is particularly problematic as their tendency to dig backwards (using the hind-foot "spade" tubercle) and the abrasive nature of many soils need to be taken into account. Thus, very little literature exists regarding their terrestrial habits. In 2009 and 2010, we conducted a study on this species that specifically sought data on upland habitat use over the course of entire active seasons (approx. 4 months from May to August). These data were considered critical to crafting and evaluating management plans for this species at its northern limit in British Columbia, Canada. The average weight for animals in this population was 19.6 ± 3.5 g, so transmitters considered suitable for deployment had a maximum lifespan of 21 days (BD-2 external radio-transmitter, Holohil, Carp, Ontario). Surgical implantation of transmitters was not considered an option, as multiple transmitters needed to be affixed to individual animals over the course of each active season to allow extended tracking. Preliminary tests on captive animals with conventional belt-attachment transmitters (Bartelt and Peterson 2000; Griffin and Case 2001; Bull 2006) indicated potential problems with field use. The transmitters would migrate to the ventral surface of the animal, and appeared to prevent normal digging behavior by impeding movement and/or riding up on the body when the animals were digging (*cf.* Bartelt and Peterson 2000), and substrate clinging to the transmitter acted as a source of abrasion on the animals' skin. We therefore created an external transmitter attachment system that used a novel material while deviating from the traditional belt design. We describe this procedure herein, as it proved generally successful and allowed us to collect important data in the field.

Material & Design.—We constructed the harness for the transmitter using Opsite™ FlexiFix™ transparent film. This thin, smooth material is a waterproof, adhesive wrap used to treat humans with burns or other injuries. It can be folded and rolled, thus allowing it to be formed into soft "cords" that we used in the attachment process. Prior to our field work, Opsite™ FlexiFix™ transparent film was compared to polyethlylene

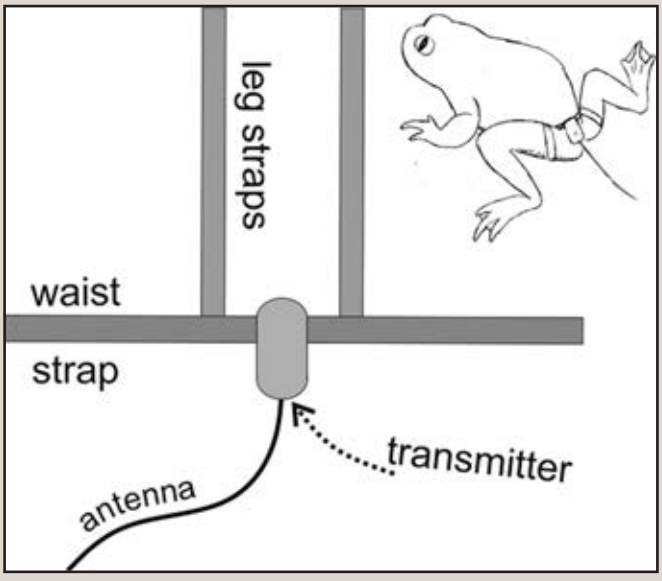

FIG. 1. Schematic of harness package consisting of three pieces of FlexiFix™ folded into straps with a transmitter (not drawn to scale). The waist strap is threaded through an opening built into the housing of the transmitter, and then the leg straps are attached using very small amounts of Krazy Glue®.

FIG. 2. (a) Ventral view of spadefoot in final stages of harness attachment. To protect the animal, a strip of FlexiFixTM (see arrow) is placed under the belt and leg straps at points of gluing. This strip is removed once the glue has dried. (b) Posterior of spadefoot showing leg straps in place to prevent lateral movement of the transmitter.

tubing and silk ribbon using captive spadefoots. FlexiFix™ was selected based on its softness, flexibility, and malleable nature.

Our primary modification to the typical belt design for anuran transmitters was the addition of leg straps that created a harness-type device. These leg straps prevented the transmitter from ventral rotation, and from riding up anteriorly as when the spadefoot was digging into the soil.

We constructed the waist and leg straps from three separate pieces of FlexiFix™: one 1.5 × 8 cm piece for the waist and two 1–1.5 × 5 cm pieces for the legs. Each piece was folded into straps by peeling the white backing off the material and continually folding the adhesive layer back onto itself (≈ 2.0 mm width) until the entire piece had been used. Care was taken to ensure no creases or bubbles formed in the strap, producing a flat, smooth surface (fine-tipped tweezers were useful during this stage). We first attached one of the leg straps to the waist strap using a small amount of Krazy Glue®. Following this, either a 0.66 g (16-day life) or 0.72 g (21-day life) BD-2 external radio-transmitter was threaded onto the waist strap using a small tube (2 mm diam) built into the encasement of the transmitter. The second leg strap was then also attached onto the waist strap producing the harness (Fig. 1). At this point, the harness packages for the two sizes of transmitters weighed 0.87 ± 0.07 g and 0.94 ± 0.09 g, respectively. Note that these weights decreased by ≈ 0.1 g once excess strap material was clipped off the harnesses upon fitting them to animals (see below). We constructed these transmitter-harness packages prior to heading into the field, as assembly time for each harness was 30–45 min. A short video demonstrating the construction of a harness is available at http://vimeo.com/92669521 (password: spadefoot).

Deployment in the field.—Radio-transmitter harnesses were attached to 19 adult spadefoots that were tracked for varying durations (4–90 days) from 10 June–7 Sept 2009, and 17 May–26 Aug 2010. The selection of animals for transmitter attachment was based on individual body mass, as weighed to the nearest 0.1 g with a digital scale. Transmitter and harness packages did not exceed 6% of body weight and most were < 5% (Bartelt and Peterson 2000).

Attachment of the transmitter harness to a spadefoot required two people, one to position the animal (ventral side up) and the other to attach the harness (Rathbun and Murphey 1996). Once the animal was in the proper position, a protective slip was placed on the belly towards the pelvic area to ensure glue did not come in contact with the individual's skin (Fig. 2). We used a piece of FlexiFix™ for this precaution, but any comparable material could be used. The harness waistband was wrapped around the waist and secured with a small drop of glue. The ideal fit of the waistband was such that it would not pull off over the animal's hind legs while not pinching the skin. The leg straps were then wrapped around the legs of the animal and fastened in the same manner (Fig. 2). The leg straps fit looser than the waistband, but were tight enough to prevent the hind foot from becoming lodged in the harness when digging. Once the harness was fully fitted, excess waist and leg strap material was cut and all attachment points were checked to ensure the glue was dry before the protective slip was removed. Study animals were re-hydrated in a container of water prior to compensate for a loss of important stored fluids (see Shoemaker et al. 1969). Note that fluid loss during handling was very common, and this prevented us from calculating the precise weight of the transmitter-harness package once it was fully-fitted and excess strapping had been removed. Still, the average weight gain of the animals from the attachment of the 0.72 g transmitters (used 82% of the time, 45/55 attachments) was 0.63 ± 0.2 g (range = 0.0–1.0). The entire field procedure took approximately 10–15 minutes from capture to release, with a marked drop in timing with experience.

We conducted routine telemetry checks on the animals every one to three days (average = 1.5 days). Given the novelty of the attachment method, we took the precaution of examining closely the telemetered animals every week (in Year 1) or every other week (Year 2) to detect complications. This required locating and handling the spadefoots (normally at night, when they were active). If the harness fit well and no injuries were evident, the animal was released within 1–3 minutes of capture. If abrasions/skin sores were evident the transmitter was removed, the wound was cleaned with distilled water and the animal was released. Using the same procedure, each telemetered animal was briefly re-captured 2–3 days before the projected expiration date of the battery, and refitted with a new transmitter-harness package

FIG. 3. (a) Telemetered spadefoot showing the normal position of the transmitter, with the antenna pointing away posterior from the animal. (b) Spadefoot in daytime retreat showing how the antenna (see arrow) has flipped anteriorly above the animal. The location of completely buried animals often could be determined by the antenna protruding out of the substrate.

provided that no problems were detected. On average each spadefoot received 3 ± 1.6 transmitters (range = 1–5).

Results and Discussion.— Using the method described herein, we tracked 19 spadefoots from 4 to 90 days successfully ($\bar{x}\approx$ 50 ± 28.2 days). All telemetered animals were recorded entering and emerging from burrows, and the antennae often allowed for the precise relocation of individuals (even after transmitter failure), as they would protrude out of the soil above buried animals (Fig. 3). Detection distances using telemetry were substantial (up to 800 m away); considerable movements also were recorded, with animals covering distances up to 1.1 km over an active season (Garner 2012). The spadefoots also appeared able to successfully orientate on the landscape, often returning to previously-used burrows (Garner 2012).

Similar to that reported for the traditional "belt" design, some injuries to the study animals were detected. Rubbing and/or waist abrasions, ranging from a slight chafing of the skin to small cuts on the waist, were detected on five individuals (26%). Goldberg et al. (2002) suggest that terrestrial amphibians might be more prone to abrasions from telemetry belts due to the lack of water to wash away granular material stuck under harnesses. Reported abrasion rates from studies on mainly-terrestrial anurans are wide ranging, including 0% (Miaud et al. 2000), 18% (Bartelt and Peterson 2000), 22% (Griffin and Case 2001), 52% (Constible et al. 2010), and 75% (Goldberg et al. 2002). Several other studies do not mention injuries inflicted by attachment processes (Muths 2003; Bartelt et al. 2004; Forester et al. 2006), or they report abrasions but not the rate of occurrence (e.g., Bull 2006). Admittedly, the assessment of telemetry success was not the focus of these papers, but without these data it becomes difficult to compare abrasion rates over a large number of similar studies. Despite this, our abrasion rate falls within the lower range of observed rates for terrestrial anurans.

Average time to detection of abrasions on five animals was 44 ± 25 days (N = 5; range = 11–71) and was typically after multiple transmitter exchanges and re-fittings. For those animals that never displayed abrasion, average tracking duration was 56 ± 31 days (N = 10; range = 10–90). Despite the attention given by field personnel, it is possible these injuries were caused by an improperly-fitting harness (i.e., too tight or too loose); we likely prevented abrasions on two animals that had their harnesses replaced the day after attachment when it was noticed that the fit was suboptimal. Also of note is the fact that two animals that developed abrasions did so during a period of extended time when we could not locate and inspect them due to failed transmitters (10 and 18 days of wearing harnesses, respectively). Abrasions on these animals were detected when visual searches and knowledge of the past habits of the animals allowed for their recapture (Garner 2012).

We detected three spadefoot mortalities during our study that to some degree may be attributed to the transmitter-harness package. In these cases, abrasions did not appear to be the cause of death, as no superficial injuries were observed on the deceased animals. Rather, on two animals the transmitters appeared to have been embedded in hardened soil, and on the third animal the harness was caught on a root; both situations appeared to have prevented the animal from returning to the surface. Of note here is that our study animals occupied a landscape dominated by heavy clay soils that hardened quickly after rainfall; sandier or more friable soils may have been less problematic. Somewhat analogous results have been observed for aquatic anurans where transmitter and/or belt entanglement on aquatic vegetation caused animals to drown (Rathbun and Murphey 1996; McAllister et al. 2004). Although researchers generally aim to minimize disturbance to their study animals, we agree with Bartelt and Peterson (2000) that in the case of anurans, frequent assessment of each animal's health and condition is necessary to ensure the proper fit of the belt and to prevent and/or detect injuries. Spadefoots are a good example of an anuran that can fluctuate considerably in weight (and waist size) depending on environmental conditions and food intake (Dimmitt and Ruibal 1980): well-fitted harnesses/belts may become ill-fitting in a relatively short period of time. We observed both increases and decreases in weight among individuals carrying transmitters. The average change in weight for telemetered animals in our first study year was -0.8 ± 2.2 g (N = 4), and in the second year it was +0.4 ± 1.7 g (N = 10); placing captive spadefoots in water often produced a quick weight gain, so likely similar fluctuations occur in the wild. In general, researchers need to balance precaution with minimizing the invasiveness of telemetry. We observed

some decrease in abrasion rates between the first and second years of our study (3/7 and 2/12, respectively; $\chi^2 = 1.56$, $df = 1$, $P = 0.21$), suggesting further experience might reduce the rate even more so. We recommend that whenever possible, transmitter attachment should be practiced and tested on captive animals to ensure the investigator is able to attach a well-fitting transmitter in the field.

Overall, our harness-design method of transmitter attachment proved successful in that we were able to follow individuals long enough to firmly establish summer habitat use, and even selection of overwintering sites (Garner 2012). In addition to providing insight into the ecology of these animals, the data were pivotal in establishing specially designated land around known breeding sights. Although not infallible, the judicious use of telemetry, including options for re-attachment of transmitter packages, can provide data critical to the conservation of species such as spadefoots.

Acknowledgments.—This work was conducted under British Columbia Ministry of Environment permit number VI09-54358, and was approved by the Thompson Rivers University Animal Care Committee, protocol no. 2009-05. Funding for the research was provided by the Natural Sciences and Engineering Research Council of Canada, the Grasslands Conservation Council of British Columbia, the British Columbia Ministry of Environment (Ministry of Natural Resource Operations), the Habitat Conservation Trust Fund, and the British Columbia Conservation Foundation. Special thanks are extended to Roger Packham for facilitating the study and to Kristine Teichman for suggesting the use of FlexiFix™.

Infection Prevalence in Three Lowland Species of Harlequin Toads from the Threatened Genus *Atelopus*

Atelopus, a species-rich Neotropical genus within the family Bufonidae (Lötters 1996), is distributed from Costa Rica south to Bolivia and eastward into the Guyanas (La Marca et al. 2005). Despite declines and disappearances of *Atelopus* species occurring before *Batrachochytrium dendrobatidis* (hereafter, *Bd*) was described (Longcore et al. 1999), *Bd* has been implicated in losses (La Marca et al. 2005; Lampo et al. 2006). The majority of these species occur in the Andes Range above 1500 m, and are considered one of the most threatened genera of amphibians worldwide. At least 71% (69 of 97) of *Atelopus* species are listed as Critically Endangered or Extinct (IUCN 2015). Still, many species have uncertain conservation status because they remain undescribed (Coloma et al. 2010) or because they require systematic revision (Lötters et al. 2011). The most affected species within the genus occur along mid-to-high elevation streams with nearly 75% of those species facing serious declines (La Marca et al. 2005). Colombia harbors the highest number of *Atelopus* species (Lötters 1996) and, similar to other parts of its distribution, nearly all species that occur in the mid-to-high elevations have declined sharply (Rueda-Almonacid et al. 2005). In the Colombian lowlands, however, species still persist at altitudes ranging from 0–600 m and there are no reported declines in this group (Rueda-Almonacid et al. 2005). This difference in survival is usually attributed to *Bd* not being able to survive well at lower elevations, which in the tropics usually means higher and less variable environmental temperatures. In order to evaluate whether *Bd* can be considered as a potential threat for *Atelopus* species, we assessed *Bd* prevalence and infection intensity on three lowland species that occurring between 5–115 m elevation, examining live animals during contemporary field surveys in 2007 to 2012 and archived museum specimens collected between 1968 and 2000.

We studied three *Atelopus* species occurring in three different localities in the coastal forests of Colombia (Fig. 1). We visited each site 3–5 times between 2007 and 2012 (Table 1). *Atelopus* aff. *elegans*, from Gorgona Island (2.966667°N, 78.166667°W; 6–115 m elev.) was sampled three times (July 2007, July 2010, and June 2012). *Atelopus spurrelli*, in the municipality of Arusí (5.566667°N, 77.5°W; 90 m elev.) on the Pacific coast was sampled five times (May and November 2009, June and September 2011, and June 2012). *Atelopus* aff. *limosus*, an undescribed species occurring near the municipality of Capurganá (8.6°N, 773333°W; 150 m), close to the border between Panama and Colombia, was sampled three times (September 2008, October 2009, and July 2012).

Survey teams composed of 2–5 people conducted field trips to each locality for 2–8 days per trip. To maximize capture success, we surveyed along streams and along forest trails using visual encounter surveys (Heyer et al. 1994). For each animal we collected the following information to look for potential

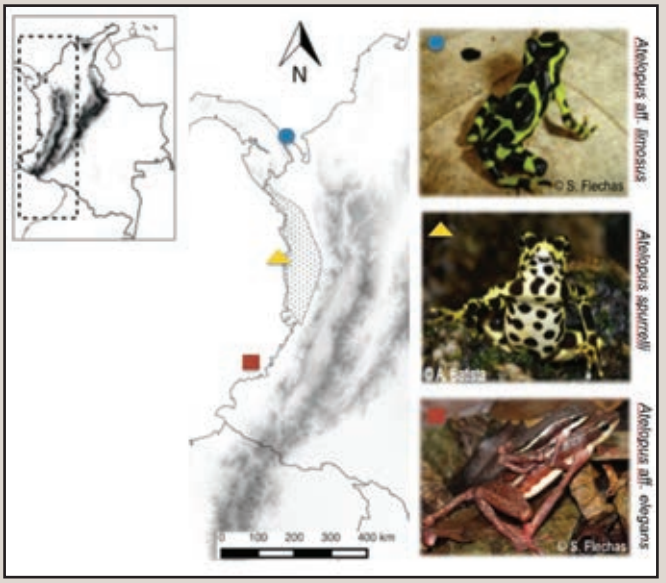

FIG. 1. Colombia locations of the *Atelopus* field sites: (■) *Atelopus* aff. *elegans*; (●) *Atelopus* aff. *limosus;* and (▲) *Atelopus spurrelli*. The distribution of *A.* aff. *elegans* is restricted to Gorgona Island near the Pacific Coast of Colombia, the distribution of *A.* aff. *limosus* is unknown, and the stippled area is the distribution of *A. spurrelli* (IUCN 2015).

TABLE 1. *Batrachochytrium dendrobatidis* prevalence among three lowland *Atelopus* species in Colombia. The number in parenthesis represents the number of *Bd*-positive individuals. p/h = person/hours. Prevalence CI 95% = Prevalence of infection, in parenthesis are the Bayesian Credible Intervals based on 95% confidence. Bold numbers indicate summaries per species.

	1969	91	0
	1983	31	0

patterns in *Bd* occurrence: sex and life-stage (male, female; adult, juvenile), snout–vent length (mm), and weight (g). To examine the hypothesis that lowland conditions may be unsuitable for *Bd* occurrence, body temperature was measured using an infrared thermometer (OAKTON ® InfraPro) with a resolution of 0.2°C. From a distance of 50 cm, we pointed the laser to the frog's dorsal surface or the exact place where the individual was perched before handling.

To determine infection status and to avoid cross contamination, animals were collected using clean, decontaminated equipment, individually handled with fresh disposable gloves, and placed in individual bags prior to obtaining the skin swab samples. Each animal was sampled by running a synthetic cotton swab (skin swabs) over the ventral surface, the inner thigh area and the plantar surface of the hind-feet webbing for a total of 50 strokes. Skin swabs were preserved either in 96% ethanol or were air dried and stored at -20°C until processed. To diagnose *Bd* infection we used two techniques: end-point PCR and Real-time TaqMan PCR – qPCR. When we started the surveys our main goal was simply to determine *Bd* presence and thus we ran end-point PCR and qPCR assay to determine presence/absence of the pathogen. Starting in 2012 we performed qPCR assay, to test not only for the presence of *Bd* but also for the infection intensity (pathogen load) and report it as the relative number of zoospores (Zoospore Equivalents, ZE) on each animal.

For end-point PCR, DNA was extracted using GeneReleaser® (Bioventures Inc., Carlsbad, California, USA). We used the primers developed by Annis et al. (2004) to amplify the ITS1-ITS2 region specifically in *B. dendrobatidis*: Bd1a (5'- CAGTGTGCCATATGTCACG-3') and Bd2a (5'-CATGGTTCATATCTGTCCAG-3'). Amplifications were performed in an MJ Research Peltier Thermal Cycler (PTC-200), as follows: an initial 2 min denaturation at 95°C, followed by 35 cycles of DNA amplification (45 sec at 95°C, 45 sec at 55°C, and 1 min at 72°C), and a final extension at 72°C for 10 min completed the amplifications. Each reaction consisted of 0.5 μL of each primer (1 μM), 3.0 μL of doubly distilled DNA-free water, 6 μL of GoTaq® Green Master Mix (1X; Promega) and 2 μL of the DNA extract. The amplified fragments were separated by electrophoresis in 1% agarose gels. The qPCR assay was performed using a BIO-RAD PCR machine (to diagnose) and an Applied BioSystems 7300 Real Time PCR System (to quantify zoospore loads). For the qPCR, DNA was extracted using PrepMan Ultra. Extractions and qPCR's were performed following the methods described by Hyatt et al. (2007) and Boyle et al. (2004). Each reaction consisted of 0.45 μL of each primer (50 μM), 5.975 μl of water, 12.5 μl of TaqMan, 0.625 μL of MGB Probe and 5 μl of the DNA template. To quantify infection intensity we used standards of known concentrations and negative controls.

To determine the historical presence of *Bd*, we swabbed museum specimens of *A. spurrelli* and *A.* aff. *elegans*. Specimens for *A.* aff. *limosus* were not available (Table 2). We used the molecular methods and protocols described by Cheng et al. (2011). In order to decrease the chances of contamination we rinsed each frog with 70% EtOH and we used fresh gloves for each frog handled. We ran a synthetic cotton swab (MWE 113) over the ventral surface, inner thighs, abdomen, and between toes for a total of 30 strokes. DNA was extracted using Prepman Ultra. Each sample was run in triplicate by using qPCR assay following Boyle et al. (2004) using an Applied BioSystems 7300 Real Time PCR System.

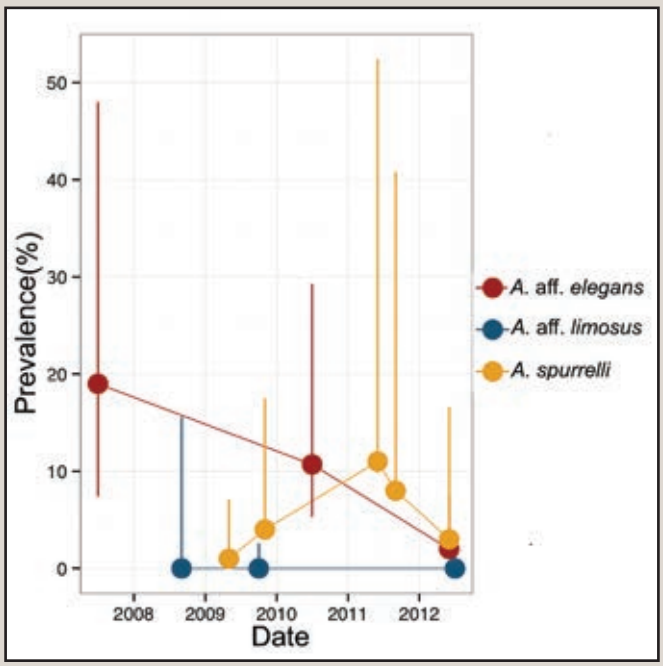

FIG. 2. Prevalence of *Batrachochytrium dendrobatidis* infection over time for the three *Atelopus* species from Colombia. Lines indicate the Bayesian Credible Intervals.

We analyzed skin swabs from a total of 658 individuals collected during the field surveys, including 308 *A.* aff. *elegans*, 178 *A.* aff. *limosus*, and 172 *A. spurrelli* (Table 1). We analyzed for *Bd* presence with 384 samples (end-point PCR and qPCR), and *Bd* zoospore equivalents or infection intensity with 274 swabs (qPCR assay). In total we detected *Bd* in 6 (3.5%) *A. spurrelli* and 27 (8.7%) *A.* aff. *elegans*. We have infection intensity data for four samples taken in 2012: one male *A. spurrelli* (16.9 ZE), two males (63 and 65490 ZE) and one juvenile (726 ZE) *A.* aff. *elegans*. Per sample date, the prevalence of the infection (i.e., the number of infected animals out of the total number of individuals sampled) was very low, ranging from 1–11% in *A. spurrelli* and from 2–19% in *A.* aff. *elegans* (no *Bd*-positive *A.* aff. *limosus*). From 2007 to 2012, the prevalence of *Bd* in *A.* aff. *elegans* dropped steadily (Table 1) (G-test test of independence with Williams' correction, $\chi^2_{df=2}$ = 19.792, $P = 5.037 \times 10^{-5}$); conversely, there was not a discernible pattern in the prevalence of *Bd* in *A. spurrelli* during that same time frame (G-test, $\chi^2_{df=4} = 2.325$, $P = 0.6762$) (Fig. 2). Visual checks of animals that were released after capture did not reveal any signs of chytridiomycosis in any species. We found that *Bd* prevalence was not influenced by body size (N = 658, $Z = 1.067$, $P = 0.286$). However, in *A.* aff. *elegans* the prevalence was higher for males ($\chi^2 = 11.412$, $df = 2$, $P = 0.003$). Frog body temperatures ranged between 23.2–28.2°C ($\bar{x}$ = 25.1°C) in *A.* aff. *elegans*, 22.6–29.3°C ($\bar{x}$ = 25.2°C) in *A.* aff. *limosus*, and 22.5–28.5°C ($\bar{x}$ = 25.4°C) in *A. spurrelli*. We detected differences in body temperature among surveys only for *A.* aff. *limosus* ($F = 136.5$, $P < 0.01$). To provide a retrospective view of *Bd* emergence, we swabbed available museum specimens: 128 formalin-preserved specimens of *A. spurrelli* collected between 1968 and 1983 and 137 *A.* aff. *elegans* collected between 1968 and 2000 (Table 2). We detected *Bd* presence in three (12%) *A.* aff. *elegans* collected in 2000.

Visual encounter surveys showed that from 2009 to 2012, *A. spurrelli* were encountered at a much lower rate. We spent approximately 414 h (person hours) surveying for individuals of *A.* aff. *elegans*, and 168 h and 468 h for individuals of *A.* aff. *limosus* and *A. spurrelli*, respectively. By the end of the study, *A. spurrelli* were difficult to find despite intense effort (Table 1). Our findings suggest a decrease in abundance of *A. spurrelli* during the course of our study. We first detected *Bd* in one of 74 frogs sampled in 2009 in the wild, then in the following surveys (2009–2012), *A. spurrelli* became increasingly harder to find. Although we acknowledge that we did not conduct systematic population abundance monitoring, we did not detect chytridiomycosis and *Bd* prevalence from our samples was low, we hypothesize that *Bd* may have contributed to the apparent decline. We cannot rule out the possibility that this drop in abundance over the time frame sampled might be due to other factors, including natural population variation (Pechmann et al. 1991). The apparent decline of *A. spurrelli* is puzzling due to the presence of cutaneous bacteria with antifungal properties (Flechas et al. 2012), the fact that these frogs occur in an environment with relatively high temperatures (22.6–29.3°C) which may be unsuitable for optimal *Bd* growth (Johnson et al. 2003; Piotrowski et al. 2004), and no observed habitat degradation or other stressors. Based on our retrospective study of museum specimens, we found no evidence of *Bd* presence in this species before the first positive record in 2009. Unfortunately, the lack of systematic population surveys makes it hard to compare abundances between years, which would allow for detecting gradual versus sudden population collapse. Other species of *Atelopus* have declined due to habitat destruction and not *Bd* (Tarvin et al. 2014), but we found no indication of habitat alteration or disturbance in our study area. Therefore we suggest that systematic surveys (population monitoring and disease diagnostics) be conducted to assess the current status of *A. spurrelli* from Arusí in order to more accurately estimate future trajectories for this population.

A recent study conducted on the same three *Atelopus* species that are the focus here revealed that *A.* aff. *elegans*, the species that we found to be most common despite *Bd* infection, harbors the highest proportion of bacterial isolates with anti-*Bd* activity; these bacteria also exhibited the strongest anti-*Bd* effect (Flechas et al. 2012). An alternative explanation for species survival when exposed to lethal strains of *Bd* could be an environmental effect that limits *Bd* growth (Rowley and Alford 2007; Bustamante et al. 2010; Zumbado-Ulate et al. 2014). Various studies have proposed the existence of climatic refugia from chytridiomycosis-driven amphibian declines (Puschendorf et al. 2011; 2013) as a mechanism to allow susceptible species to persist despite infection (Puschendorf et al. 2005). Our three study species occur in tropical coastal forests that exhibit high temperatures, above the optimal physiological range of the pathogen (Johnson et al. 2003; Piotrowski et al. 2004). This temperature regime might limit *Bd* growth causing a decrease in zoospores production, thereby slowing transmission rates and allowing individuals the time to mount an immune response or simply tolerate the pathogen. However, we suggest that when the pathogen first arrives it could cause high mortality in the naïve populations.

Knowing the relative time frame of the emergence of a pathogen in host populations is important for understanding present-day disease dynamics (Briggs et al. 2010; Vredenburg et al. 2010). For example, host pathogen dynamics can move from unstable dynamics soon after pathogens emerge in naïve host populations (e.g., epizootic state) to more stable dynamics long after emergence events (e.g., enzootic state). As part of our study, we provide a retrospective view of *Bd* emergence in two of our

three study species (specimens were not available for the third species). We sampled museum specimens using a molecular technique that has been shown to accurately reflect *Bd* presence or absence in specimens collected up to a century ago (Cheng et al. 2011; Rodriguez et al. 2014). We first detected *Bd* in three of 25 individuals of *A.* aff. *elegans* collected in 2000. Since there is a lack of sampling between 1987 and 2000, we cannot discard the possibility that *Bd* arrived to the island earlier. The elapsed time could fit an enzootic pattern of host/pathogen dynamic, where *A.* aff. *elegans* populations remain stable despite the presence of the pathogen.

Atelopus aff. *limosus,* our third study species, occurs near the border between Colombia and Panamá. This species is believed to have a wider distribution in the Darién region of Panamá (R. Ibáñez, pers. comm.), and this area was considered until recently one of the last *Bd*-free areas in Central America (Rebollar et al. 2014). Our data from 2008 to 2012 did not find any evidence of *Bd*, supporting the idea that the pathogen has not arrived to Capurganá. However, the situation is critical because *Bd* was detected in 2012 in the Darién Province in Panamá (Rebollar et al. 2014) very close (~50 km) to our study site in Colombia. We predict that *Bd* will spread across the Colombian border very soon. The fact that this is a *Bd*-naïve area and the high infection susceptibility reported for the genus, we believe that *Bd* may have a considerable impact on the *Atelopus* aff. *limosus* population. However, we also expect that the suboptimal environmental conditions (i.e., high temperatures) will limit *Bd* growth and colonization rate, which may allow for host tolerance of the infection or evolution of host resistance allowing for coexistence between host and pathogen.

Acknowledgments.—For assistance in the field we thank A. Batista, L. Barrientos, G. Corredor, A. J. Crawford, T. Escovar, C. Guarnizo, M. González, J. A. Hernández, J. Méndez, A. Muñoz, A. Paz, A. Rodríguez, P. Rodríguez, C. Sarmiento, C. Silva, F. Vargas-Salinas, and B. Velásquez. We would like to thank J. D. Lynch at the Instituto de Ciencias Naturales – Universidad Nacional de Colombia for allowing us to swab museum specimens under his care, and A. J. Crawford, V. Ramírez, and C. Sarmiento for their assistance in swabbing. We thank C. Sarmiento and S. Ellison for assistance in the laboratory and A. Paz for creating the distribution map. We would like to thank the personnel at Parque Nacional Natural Gorgona for logistic support. This study was completed with financial support from US Fish & Wildlife Service – Wildlife without Borders (96200-0-G228), Association of Zoos and Aquariums – Conservation Endowment Fund (08-836), Conservation International Critically Endangered Species Fund, and National Science Foundation (IOS-1258133). Procedures for capture and handling of live animals in the field were approved by the Colombian National Parks Authority and the Ministry of the Environment, under permits DTSO 019-09, DTSO 001-09 and Nº 10 March 7, 2012. We would like to thank D. Olson, S. Lötters, and an anonymous reviewer for helpful comments and suggestions that greatly improved this manuscript.

Ranavirus Detected in *Lithobates clamitans* and *L. catesbeianus* in Indiana

Ranaviruses are an emerging group of pathogens that threaten populations of all three classes of ectothermic vertebrates, especially amphibians (Gray and Miller 2013; Duffus et al. 2015). Infections have now been documented on six continents and in more than 175 species, and are very likely under documented (Duffus et al. 2015). The pathogenicity and broad host range of ranaviruses make them serious threats to both wild and captive populations of ectothermic vertebrate species worldwide. Despite an increased awareness and study of ranaviral infection, much remains unknown about many aspects of their ecology, including geographic distribution.

To date, the distribution of ranavirus in Indiana, USA, is poorly known. Only two studies have tested wild amphibian and reptile populations for the presence of ranavirus (Currylow et al. 2014; Winzeler et al. 2015). In south-central Indiana, Currylow et al. (2014) found PCR evidence of ranavirus in Eastern Box Turtles (*Terrapene carolina carolina*) and larval amphibians (*Ambystoma* sp and unidentified anuran larvae). Overall, ranavirus infections were detected in 2.2% of larval amphibians and 3.0% of Eastern Box Turtles sampled. However, Winzeler et al. (2015) found no SYBR quantitative realtime PCR (qPCR) evidence of ranavirus in Green Frog (*Lithobates clamitans*) tadpoles at five sites distributed across Indiana. In a third study, Kimble et al. (2014) report the presence of ranavirus in a wild-caught, newly captive population of Eastern Box Turtles that was likely initially infected in the wild. Although these studies provide some evidence that ranaviruses are present within Indiana, there is a need for broader surveillance to improve our understanding of ranavirus distribution. Our objective was to test for ranavirus infections in larval Green Frogs and American Bullfrogs (*L. catesbeianus*) from 15 sites distributed across Indiana.

In 2013 and 2014, the Indiana Department of Natural Resources collected live larvae in an ad hoc manner using dipnets or seines from 15 public areas distributed across the state (Table 1, Fig. 1). Field equipment was disinfected between sites with 0.75% Nolvasan (2% chlorhexidine diacetate; Fort Dodge Animal Health, Fort Dodge, Iowa; Bryan et al. 2009). Individuals were euthanized with a 30-minute soak in a 3% solution of neutral-buffered tricaine

methanesulfonate (MS-222; Argent Laboratories, Redmond, Washington) and stored in 70% ethanol. In the laboratory, individuals were identified to species following the methods of Hoverman et al. (2015). Kidney and liver tissue was dissected from up to 100 randomly selected individuals of each species at each sampling location. Dissection equipment was disinfected with 10% bleach between each tadpole. To minimize processing costs while maintaining reasonable sensitivity (Muñoz-Zanzi et al. 2006), we aggregated the kidney and liver tissue samples into groups of up to five individuals of a species from a site (Table 1).

DNA was extracted using a standard phenol-chloroform-isoamyl alcohol extraction method. Purified DNA was resuspended in 50 μL of TLE. A 97 bp portion of the FV3 major capsid protein (MCP) was amplified by qPCR as previously described in Kimble et al. (2014). A synthetic strand of MCP DNA (gBlocks Gene Fragments, Integrated DNA Technologies, Coralville, Iowa) was used to make serial dilutions for a standard curve. Two negative controls (i.e., pure water) were also included. Quantitative PCR was conducted using a CFX Real-Time qPCR thermocycler (Bio-Rad Laboratories, Hercules, California). All standards and unknowns were amplified in technical duplicate. If only one duplicate was positive in a PCR, the sample was considered putatively positive. In this case two more duplicates were amplified and the sample was considered positive if again at least one duplicate was positive. In the case of a disagreement between runs, a third pair of duplicates was amplified and a majority rule among runs was applied to call samples qPCR positive or negative; 17.9% of samples were rerun once and 5.8% required a third run.

We screened 322 aggregate samples representing 1599 individual larvae (956 green frog and 643 bullfrog). There was no evidence of die-offs at any sampling site, yet ranavirus was detected at twelve of the fifteen sampled sites (Table 1). Aggregate samples of green frog larvae were ranavirus-positive at seven of the ten sites where green frogs were sampled. At these sites, we detected ranavirus in 11–100% of the Green Frog aggregate samples tested per site. Aggregate samples of American Bullfrog larvae were ranavirus positive at five of the seven sites where they were sampled. At these sites, we detected ranavirus in 11–65% of the aggregate samples tested.

Our results suggest that ranaviruses may be present across disparate sites (Fig. 1) and site types in Indiana, but that prevalence may vary widely. Infections were detected in wildlife areas, state parks, fish hatcheries, and lakes sampled across the state. This work expands on previous research examining ranavirus in Indiana (Currylow et al. 2014, Winzeler et al. 2015), which demonstrated low to undetectable levels of ranavirus (≤ 3% prevalence) in wild larval amphibians and wild adult Eastern Box Turtles in south-central Indiana. Additionally, Kimble et al. (2014) documented ranavirus infections in a southwestern Indiana population of Eastern Box Turtles that was moved into captivity. Prevalence in this captive population eventually reached 94% (S. Kimble, unpubl. data). Studies in Indiana, therefore, have estimated a large prevalence range (0–94%), typical of surveillance studies conducted in other regions of the United States wherein site-level prevalence of ranavirus ranged from 0.3–84% (Gahl and Calhoun 2008; Todd-Thomas 2010; Hoverman et al. 2012a; Hoverman et al. 2012b; Allender et al. 2013; Sutton et al. 2014). These data suggest that ranavirus may be widespread in Indiana, yet there is a need for more research to document infection prevalence at the population-level for the broad diversity of amphibian and reptile species in the state.

Acknowledgments.—We acknowledge the assistance of Sarabeth Klueh-Mundy, Jason Mirtl, Mikey Hiatt, Daniel Snyder, and George Meindl for sample collection and processing. Support was provided by the Indiana Department of Natural Resources (IDNR), Division of Fish and Wildlife, Wildlife Diversity Section, State Wildlife Improvement Grant E2-14-WDP001. All samples were collected by IDNR, obviating the need for any permits or protocols to be held by the authors.

Batrachochytrium dendrobatidis Dynamics in an Isolated Northern Leopard Frog (*Lithobates pipiens*) Population in Arizona

North American ranid frogs are experiencing population declines in several western species, often resulting in state or federal protection (Clarkson and Rorabaugh 1989; Hale et al. 2005; Rachowicz et al. 2006; Southwest Endangered Species Act Team 2008). The Northern Leopard Frog (*Lithobates pipiens* [*Rana pipiens*]; NLF) has experienced the greatest decline in the western two-thirds of its range (Rorabaugh 2005) and was recently under consideration for listing as federally threatened or endangered in the western part of its range (Smith and Keinath 2007). Several reports implicate chytridiomycosis caused by the pathogenic fungus *Batrachochytrium dendrobatidis* (*Bd*) in the decline of western NLF populations (Carey 1993; Carey et al. 1999; Voordouw et al. 2010), whereas others have found little evidence for *Bd*-related NLF declines (Johnson et al. 2011). Our study goal was to estimate how the abundance of adult NLFs in a single Arizona, USA population changed over a five-year period in relation to *Bd* presence and prevalence.

We conducted this study in a single, isolated pond in Coconino National Forest, Coconino County, Arizona. This pond is a perennial, man-made stock tank, surrounded by Ponderosa Pine (*Pinus ponderosa*) dominated forest and cattle pasture, which is typical habitat for NLFs in Arizona (Rorabaugh 2005). Adult NLFs, Western Chorus Frogs (*Pseudacris triseriata* complex), and Tiger Salamanders (*Ambystoma tigrinum*) breed at this site for several weeks following snowmelt in late February to early March. NLF larvae develop over the summer with tadpoles typically metamorphosing in mid-June to mid-July. Adults and young-of-the-year (metamorphs) forage near pond edges over summer and typically overwinter at pond bottoms (Rorabaugh 2005).

We surveyed the population annually from June 2007 to Aug 2011 (Table 1). We conducted surveys three times annually during the mid-late summer (June, July, August) when frogs are most abundant and readily observed from the pond perimeter (Table 1). We estimated adult NLF abundance using visual encounter surveys of frogs ≥ 6 cm snout–vent length (SVL) encountered while walking the entire perimeter of the pond (Rachowicz et al. 2006). Surveys were conducted between 1000 and 1500 h to control for diel and surveyor bias in estimates. Newly metamorphosed frogs ≤ 4.5 cm SVL were not included in counts, but their presence was noted. We obtained additional evidence for breeding using egg-mass surveys conducted by wading the entire pond during breeding in late February and early March in all years except 2007 (Table 1), when the pond was inaccessible during breeding.

We opportunistically sampled adults, larvae, and metamorphs (Table 1). In each year, we swabbed animals for the presence of *Bd* at two time periods, when breeding was initiated and mid-late summer after metamorphs had emerged. We selected these two time periods to maximize the likelihood of detecting *Bd* by coinciding with the times of highest frog abundance. We captured all animals by hand, wearing disposable vinyl gloves, which were changed after handling each individual to prevent the possible spread of *Bd* and cross contamination of samples. All captured frogs and larvae were placed into individual sterile containers, swabbed (Retallick et al. 2006), and released after all captured individuals were swabbed to prevent resampling. We placed swabs in individual 2-mL screw-cap microcentrifuge tubes (USA Scientific, No.1420-9701) containing 70% ethanol, and stored them at -20°C until DNA extraction (Retallick et al. 2006).

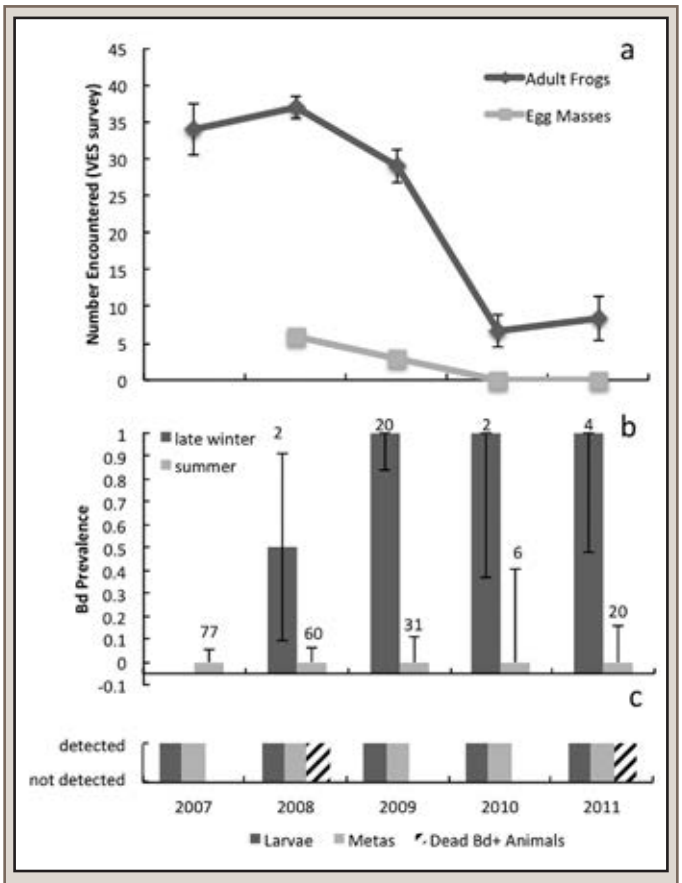

FIG. 1. Northern Leopard Frog (*Lithobates pipiens*) abundance (a; adults: mean ± 1 SE), *Batrachochytrium dendrobatidis* (Bd) prevalence (b; site-specific values during late winter and summer sampling periods), and presence of demographic indicators (c), 2007–2011 in Arizona, USA. Numbers above prevalence bars represent sample sizes; prevalence error bars represent Clopper-Pearson 95% central confidence intervals. Metas = metamorphs.

We ran samples in duplicate using an Applied Biosystems 7900HT Sequence Detection System (Hyman and Collins 2012). We included standards of 20.0, 2.0, 0.2, and 0.02 *Bd* zoospore genome equivalents (ZGE) μL^{-1} (equivalent to 100, 10, 1, and 0.1 ZGE in the total 5 µL of template added) and negative controls in each 384-well plate. We calculated the ZGE in swab extract as the mean of all Bd-positive wells, multiplied by 400 to account for sample dilutions and unit conversions. We calculated pathogen prevalence by dividing the number of infected animals by the total sample size and included 95% Clopper-Pearson binomial confidence intervals.

Abundance of adult NLFs declined from an average of 34 adults in 2007 to eight adults in 2011 (Fig. 1). Egg mass detection declined from six in 2008 to zero in 2010 and 2011, but metamorphosed frogs were present in 2011, indicating that there was some successful NLF reproduction in that year (Fig. 1).

Bd prevalence during winter breeding increased from 50% (N = 2, 95% CI: 9–91%) in 2008 to 100% in 2009 (N = 20, 95% CI: 84–100%), 2010 (N = 2, 95% CI: 37–100%), and 2011 (N = 4, 95% CI: 48–100%; Fig. 1). However, our small sample size precludes our ability to determine any clear longitudinal trends in *Bd* prevalence during the winter of each year. Overall, 27 of 222 (12%, 95% CI: 8–17%) NLF tested positive for *Bd*. These *Bd*-positive animals were all adult frogs sampled in winter (Fig. 1, Table 1). No *Bd*-positive larvae (N = 31) or metamorphs (N = 96) were detected (Fig.1; Table 1).

There were clear seasonal trends in *Bd* prevalence. Whereas 96% of animals sampled in winter (N = 28) tested *Bd* positive, no animals sampled in summer (N = 194) tested *Bd* positive (Fig. 1; Table 1).

Bd loads on positive animals varied from 10 to almost 42,000 ZGE, with a mean of 8424 (± 2069 SE) ZGE. Four dead animals were detected over the five years of surveys, one in the winter of 2008 and three in the winter of 2011 (Fig. 1). All dead animals tested *Bd* positive, and their pathogen loads (mean 3297 ± 1801 SE) were lower than those of live infected animals (mean 9433 ± 2369 SE). Live infected adults showed no obvious signs of morbidity.

Bd prevalence was high in winter breeding adults, but consistently absent from larvae, metamorphs, and adults in the summer, demonstrating clear seasonality in *Bd* prevalence, and emphasizing the importance of properly timing sampling to detect *Bd* in NLF populations. Similar seasonal reductions in *Bd* prevalence occur in other NLF populations (Voordouw et al. 2010). This seasonal reduction in *Bd* prevalence could alter adult survival (McMahon et al. 2014) and recruitment of metamorphs to adulthood (Muths et al. 2011; Scheele et al. 2015).

It is unclear whether *Bd* was present in this population before our first detection of *Bd* in 2008. Thus, although the abundance of adult NLFs decreased by over 4-fold in the years following our first *Bd* detection, we cannot determine whether the observed decline in adult NLFs was caused by the introduction of *Bd* or was fluctuation in adult abundance caused by other factors. Several adult frogs that were captured alive showed no signs of morbidity despite relatively heavy *Bd* loads (>10,000 ZGE). These loads were above threshold levels that cause death in other ranid species (Vredenburg et al. 2010). If these frogs did indeed survive these infections, it might indicate that they are either tolerant of *Bd* infections, only suffer morbidity/mortality at higher pathogen burdens, or undetected synergisms apply.

Resources for conservation are limited and must be used effectively. If NLF management plans are going to include costly *Bd*-mitigation strategies, such as captive breeding, labor-intensive monitoring, habitat modifications, or species relocations, they should also include examination of the fitness-related costs of *Bd* infection for NLFs (e.g., Voordouw et al. 2010) to refine the effectiveness of management efforts. Still, until we gain a more detailed understanding of the costs of *Bd* infections for NLFs, managers should continue to take a precautionary approach to the protection of threatened NLF populations by using a wide array of the available strategies to bolster populations against *Bd*-related decline.

A Hatchling Gopher Tortoise (*Gopherus polyphemus*) Care Protocol for Experimental Research and Head-Starting Programs

The Gopher Tortoise (*Gopherus polyphemus*) is federally threatened in its range west of the Mobile River which includes Mississippi and Louisiana, and is under consideration for federal listing throughout its entire range in the southeastern United States. Mississippi populations have been severely reduced or even extirpated from some portions of their range, and recruitment of new reproductive individuals is low (Epperson and Heise 2003). Possible factors contributing to the low recruitment rates in the species' western range are habitat loss from development and fire suppression, lack of genetic diversity (Ennen et al. 2010), low natural hatching success (Epperson and Heise 2003; Noel et al. 2012), and increased risk of predation by domestic dogs (*Canis familiaris*), Coyotes (*Canis latrans*), Nine-banded Armadillos (*Dasypus novemcinctus*), and Red Imported Fire Ants (*Solenopsis invicta*). At the Camp Shelby Joint Forces Training Center (hereafter Camp Shelby), Perry County, Mississippi, the 8–43% hatching success reported for *G. polyphemus* (Epperson and Heise 2003; Noel 2012) is much lower than the 67–97% hatching success reported in the eastern portion of the species' range (Landers et al. 1980; Smith 1995; Butler and Hull 1996). This low hatching success, combined with the range-wide estimated 94% chance of being predated before one year of age (Alford 1980; Landers et al. 1980), can result in continued local population declines and extirpation unless there are strategies devised to increase hatchling survival.

One strategy for increasing hatchling survival is to raise juveniles in captivity (Pedrono and Sarovy 2000). Head-starting can increase juvenile survival prospects by allowing tortoises to obtain larger body sizes and develop harder shells before being released; reducing the number of potential predators that can feed on them. Larger tortoises may also be stronger and more capable of digging deeper burrows, which would be beneficial in soils with higher clay content. This not only decreases the risk of predation, as deeper burrows also offer a wider range of thermoregulatory options and increased protection from fire.

As part of a larger study investigating factors that may be responsible for such low recruitment and the species' decline, *G. polyphemus* eggs were collected in 2010 from a site with low recruitment rates (Camp Shelby) and from one of Mississippi's few sites with high recruitment rates (Hillsdale). One aim of this study was to collect yolk samples to quantify maternally-deposited corticosterone, a hormone that mitigates the stress response and regulates metabolism and where elevated levels have been shown to decrease hatching success in other species (Eriksen et al. 2003; Love et al. 2005). We also planned to compare hatching success, hatchling growth rates, and behaviors such as burrow construction, basking, and feeding frequencies in hatchlings between the two sites. An important component of this work was the housing and care of captive tortoises prior to and during these investigations. In this account we describe the husbandry protocol that was developed for raising hatchling *G. polyphemus* in captivity. Additionally, we provide comparative data from a previous study at Camp Shelby which looked at survivorship among tortoises released directly after hatching to determine whether these husbandry practices are beneficial and can be adapted for other research and head-starting programs. While head-starting is not a practical solution for maintaining tortoise populations in perpetuity, it can be a useful tool if the protected and faster-growing head-started juveniles have significantly higher survivorship than wild juveniles as well as a reduced age to sexual maturity (Heppell et al. 1996). If successful, head-starting can at the very least slow down population declines and the loss of genetic diversity as effective management strategies are being devised and implemented. Herein we describe a successful husbandry protocol for *G. polyphemus* (and potentially other burrowing tortoise species) that arose from research attempting to understand the decline of this species in Mississippi.

Materials and Methods.—*Gopherus polyphemus* burrows were checked daily from 15 May to 30 June 2010 to ensure that eggs were collected within 24 hours of oviposition. Eggs were collected from Camp Shelby, Mississippi, and Hillsdale,

FIG. 1. Tortoise container with food, water, and PVC burrow. Burrows were placed in the coolest part of the tub, opposite of the basking lamp.

FIG. 2. Lighting and container arrangement in the lab.

Mississippi, USA (geographic coordinates withheld). During excavation and prior to transport, the tops of exposed eggs were marked with a graphite pencil so that they could be kept in the same orientation in which they were found; this guards against damage to the embryo following its attachment to the inside of the egg shell (Limpus et al. 1979). Eggs were placed in individual plastic containers containing vermiculite that was sterilized and dried before being rehydrated with distilled water at a ratio of 0.7 g water per 1.0 g of vermiculite (Packard et al. 1987), and then transported in a foam-lined cooler to reduce vibrations and maintain a constant temperature. Upon arrival at the University of Southern Mississippi, the eggs were weighed and measured, and then incubated at 29.3°C, a recommended temperature for producing a 50:50 sex ratio in this species (Demuth 2001).

Body mass, carapace (CL), and plastron (PL) lengths were recorded within 24 h of hatching, and individual numbers were assigned to each animal using a unique pattern of notches cut from the marginal scutes with a pair of dissecting scissors, similar to those described by Cagle (1939). Each tortoise was housed individually in a plastic tub (Rubbermaid®, Wooster, Ohio, USA) measuring 67.8 × 40.1 × 17.5 cm (L × W × H) to monitor food intake and eliminate stress from resource competition. Each tub was labeled with the occupant's number to assure that tortoises were returned to the proper tubs after measurements and soaking. All tubs contained 8 cm of sandy soil that was collected from the Hillsdale field site (Troup sand), a PVC pipe "burrow" (10 cm wide × 13 cm long) with one end plugged by an ABS test cap (to prevent the tortoises from burrowing through the back and pushing the burrow around the enclosure), and one separated petri dish (FisherScientific®, Waltham, Massachusetts; 60 × 15 mm) (Fig. 1). The petri dish lid and base were recessed into the soil and used for food and water, respectively. After one year, the water dishes were switched to larger and more durable glass culture dishes (63 × 28 mm), but plastic petri dishes continued to be used for food. Basking lamps with 125-watt Sylvania® (Osram Sylvania, Danvers, Massachusetts) brooder bulbs were placed above and in between tubs so that each lamp would heat two tubs simultaneously. This resulted in a basking zone temperature around 34°C, burrow temperatures around 21°C, and a temperature gradient between the basking and burrow areas. Fluorescent light fixtures measuring 1.2 m long with 36-watt ReptiSun® 10.0 UVB fluorescent bulbs (Zoo Med Laboratories, San Luis Obispo, California) were mounted approximately 20 cm above the enclosures so that two bulbs could light five tubs simultaneously (Fig. 2). Fluorescent lamps were maintained on a 12:12 h (light:dark) cycle, while the basking lamps were maintained on a 10:14 h cycle, coming on an hour after and then shutting off an hour before the fluorescent lights.

Between 0800 h and 1100 h each day, feces and uneaten food were removed from the tubs and petri dishes were washed with Dawn® (Proctor & Gamble, Cincinnati, Ohio) dish detergent and rinsed thoroughly before being replaced. Tortoises were provided with tap water daily (aged for one day so chlorine could evaporate), and a commercial tortoise diet (Natural Grassland Tortoise Food; Zoo Med Laboratories) was reconstituted with distilled water and provided *ad libitum*, totaling around 15 g, or one tablespoon of food daily. Initial encouragement was needed to stimulate consumption of the commercial diet, so chopped turnip, mustard, or collard greens were mixed in with the reconstituted food for the first month. After one month, when the tortoises were readily consuming the commercial diet, turnip or collard greens were offered weekly and dusted with calcium (Calcium with Vitamin $D_{3;}$ Rep-Cal, Los Gatos, California) and vitamin supplements (Herptivite™ with Beta Carotene; Rep-Cal). To promote natural foraging behavior and add variety to the diet, rye grass (*Lolium* sp.) was planted in the back of the tub away from the basking lamp (Fig. 3). Old rye grass was removed, and tubs were replanted every two weeks. Tubs were misted weekly

FIG. 5. A hatchling tortoise with transmitter from earlier Nature Conservancy research. The modified transmitters for this project had an antenna protruding from the middle of the transmitter so it would not have to be bent to face posteriorly. Pulse rates were reduced as well in order to extend the lifespan of the transmitter.

to maintain the rye grass, stimulate feeding, and reduce dust. As the tubs were being watered, burrows were refilled with soil to encourage continued burrowing behavior. To ensure hydration, tortoises were soaked weekly in groups of up to six individuals for 10 min in a tub of warm tap water deep enough to cover the lower half of the smallest individual. Body mass, CL and PL were recorded monthly when the tortoises were soaked.

After two years in captivity, hatchlings were transferred to individual 1.8 × 1.8 m outdoor enclosures (Fig. 4) from 7 June to 28 July 2012 to observe natural burrowing behavior and assess their ability to acclimate to outdoor conditions prior to their release into the wild. Each enclosure contained a shallow dish to collect water and a large section of tree bark to provide shelter and shade until the tortoises excavated burrows of their own. An irrigation timer was set to water the enclosures every two days to keep the water dishes filled and to facilitate the growth of grasses and forbs.

To provide adequate time for the tortoises to acclimate and dig suitable burrows, we released them before cold weather arrived on 1 August 2012. Prior to their release, the tortoises were excavated from their burrows, CL, PL, and weights were recorded, and burrow depth and length were measured. Ten tortoises from each site were then randomly selected to receive custom radio transmitters (BD-2; 2g Holohil®, Carp, Ontario, Canada) with the antenna rotated 90 degrees to protrude from the middle of the transmitter. The traditional design required the antenna to be bent to point towards the posterior of the tortoise, which could negatively impact transmitter performance. The pulse rate was also reduced to extend the transmitter lifespan an additional four weeks from the original 10–20 week lifespan. Transmitters were affixed to the fifth vertebral scute with a two part epoxy (Protective Coating Company's PC-7®, Allentown, Pennsylvania) (Fig. 5) and held in place with masking tape overnight while the epoxy cured. The epoxy is strong enough to prevent transmitter loss through burrowing activity, but can easily be removed without any damage to the scutes. Unlike many other epoxies, PC-7® is not exothermic and will not burn the scutes while curing.

Prior to their official release, tortoises were placed in temporary enclosures at their original site of egg collection. This technique, known as a "soft release," is meant to encourage site fidelity and prevent roaming into undesirable areas. The enclosures consisted of a 0.91 m high, 2.4 m diameter circle of hardware cloth held in place with 1.2 m long metal U-posts and secured to the ground with sod staples to prevent tortoises from pushing under the wire. Burlap was draped over the top of the entire enclosure for shading and to prevent bird and snake predation. Camp Shelby and Hillsdale each had two enclosures installed and each received eight tortoises except for one of the enclosures at Camp Shelby, which only received seven. Tortoises were then held in the pens for five days before it was disassembled and they were allowed to roam freely. Tortoises with transmitters (N = 20) were then tracked three times per week for two months using an ICOM® (Kirkland, Washington) IC-R20 receiver and a Wildlife Materials Incorporated® (Murphysboro, Illinois) three element folding antenna. After two months, The Nature Conservancy at Camp Shelby took over telemetry and continued throughout the remaining lifespan of the transmitters.

Results.—A total of 93 eggs were collected in 2010 from Hillsdale (N = 47) and Camp Shelby (N = 46). Average clutch size at Hillsdale was 5.88 ± 1.81 SD (range: 4–9) and 4.6 ± 1.07 SD (range: 3–7) at Camp Shelby. Incubation time for all eggs (N = 36) averaged 81.00 ± 3.36 days (range: 76–89), with a Hillsdale

TABLE 1. Comparison of two-year-old captive and two-year-old wild* Camp Shelby tortoises. CL = carapace length, PL = plastron length.

	Captive-reared			Wild			t-test		
	N	Mean	SD	N	Mean	SD	t-value	df	p

* = Tortoises that hatched in captivity, were outfitted with radio transmitters, released afield shortly after hatching, and tracked via radio telemetry for two years (at which time measurements reported below were taken).

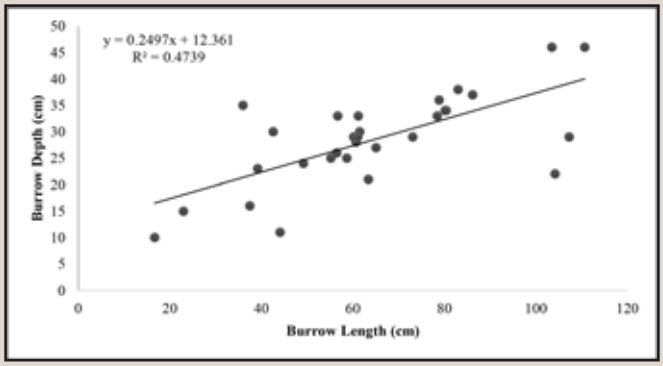

FIG. 6. Burrow depth and length after 51 days in an outdoor enclosure before release.

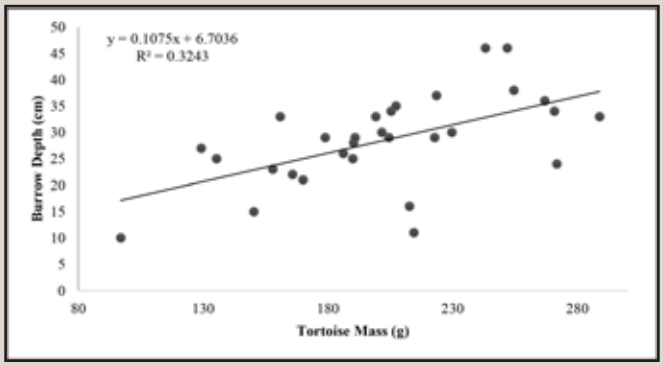

FIG. 7. Tortoise mass and burrow depth after 51 days in an outdoor enclosure before release.

hatching success of 46.8% (22/47) and 30.4% (14/46) for Camp Shelby. While a total of 36 tortoises hatched, three died within a day of hatchling, another perished in April 2011 after flipping over under its basking lamp, and one tortoise never developed full function of its rear legs, leaving 31 individuals that were eventually released. While we found no significant differences in growth rates between captive-reared tortoises from the high and low recruitment sites, captive tortoises (both sites combined) grew at faster rates than wild tortoises of the same age that were released directly after hatching and monitored via telemetry (Table 1). Although *G. polyphemus* are most likely capable of sperm storage, as documented in *G. agassizii* (Palmer et al. 1998; Pearse and Avise 2001), we assumed single paternity for each clutch and accounted for clutch effects using a blocked ANOVA. Even under this level of analysis, all variables of growth in the captive tortoises remained significantly greater than the wild tortoises: final CL ($F_{1,17.3}$ = 176.141, p <.0001), final PL ($F_{1,17.1}$ = 178.271, p <.0001), final mass ($F_{1,18.5}$ = 133.471, p < .0001), and mass gain per day ($F_{1,18.7}$ = 151.054, p <.0001). The wild tortoise data, collected by M. Hinderliter and J. Lee (unpubl. data), also shows that our captive-reared tortoises at two years of age were greater in size than two of the only known wild hatchlings still alive seven years after release (CL = 77.48 and 89.61 mm; PL= 70.96 and 82.59 mm; mass = 129.57 and 160.67g).

From outdoor enclosure observations, the time required for two-year-old *G. polyphemus* (N = 30) to construct burrows deep enough to cover the entire body ranged from 1 to 21 days with an average of 7.1 days (SD = 5.86). One two-year-old Camp Shelby tortoise remained in a pallet burrow (a shallow burrow or depression where the tortoise is still exposed) during the entire 51 day trial. These burrows were dug much quicker than those dug by a group of 2011 hatchlings (N = 26) that were placed directly into the enclosures where burrowing times ranged from 5 to 71 days, with an average of 23.2 days (SD = 17.4). We found a strong correlation between burrow depth and burrow length (Spearman rank correlation: r_s = 0.47, p < 0.0001, N = 30; Fig. 6), burrow depth and mass (r_s = 0.32, p = 0.001, N = 30; Fig. 7) and burrow depth and carapace length (r_s = 0.25, p = 0.005, N = 30; Fig. 8).

At Camp Shelby, one year after release and long after transmitters ceased functioning, The Nature Conservancy staff found that 90% (9/10) of the Camp Shelby captive hatchlings that had transmitters were still alive and all but one individual had stayed within 40 m of the release site. One of the Camp Shelby hatchlings went missing for several weeks and was assumed to have been lost due to predation or transmitter failure. However, after changing out receivers it was rediscovered, having traveled over 250 m from the release site before digging a burrow. At Hillsdale, five tortoises with transmitters were lost within a day of release due to depredation by what appeared to be a domestic dog (based on the size of the canine tracks left near the excavated burrows). After three months at Hillsdale, only two of the remaining five tortoises with transmitters could be accounted for; two were lost to depredation by a small mammal and the third possibly due to transmitter failure.

Discussion.—This husbandry protocol was initially designed to facilitate controlled investigations on the effects of stress on behavior and growth rates in hatchlings. In terms of producing tortoises for captive research and/or release with a very high survival rate, this protocol requires minimal materials for set up and is fairly low effort in terms of husbandry-related tasks. However, there are some caveats that may differ for others using this protocol. We chose a 29.3°C incubation temperature to ensure an equal sex ratio in our captive population so the effects

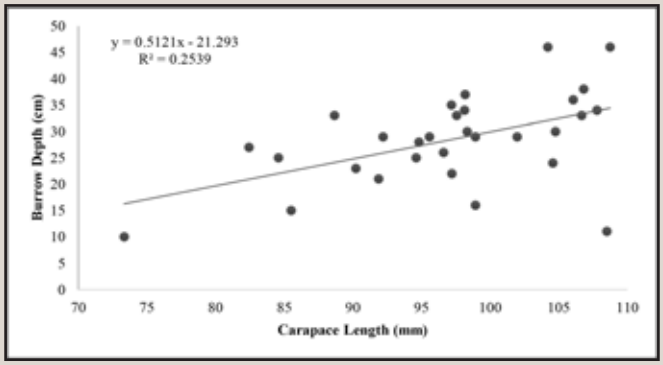

FIG. 8. Tortoise carapace length and burrow depth after 51 days in an outdoor enclosure before release.

of stress could be assessed in both sexes while eliminating the potential effects of temperature on stress response, growth rates, incubation period, and possibly behavior. However, if this protocol is to be used for head-starting programs, temperature optimums for either male (28°C) or female (31°C) *G. polyphemus* should be used since wild clutches of turtles are most often unisex (Vogt and Bull 1984; Limpus et al. 1993; Janzen 1994) and incubation at pivotal temperatures can result in intersexed hatchlings, as demonstrated in European Pond Turtles (*Emys orbicularis*; Pieau et al. 1998). When compared to typical males and females, little is known about the fecundity of intersexed individuals and this could negatively impact head-starting programs. Incubation temperatures in head-starting programs should also be considered when an equal number of males and females are desired or when producing more of one sex would be advantageous for the program. Vogt (1994) suggested that females are the limiting resource in turtle reproductive output considering that males can mate with multiple partners, and recommends a minimum of 6–8 and perhaps as many as 20 females to be released for every male.

This technique for rearing *G. polyphemus* hatchlings in an indoor setting is simple, utilizes affordable and readily available equipment, and requires minimal human contact with tortoises which can reduce stress and possibly encourage natural behavior. Although a single visit per day is all that is required for daily feeding, dishwashing, and wellness checks, one problem encountered was when the tortoises would occasionally flip onto their backs when attempting to climb the side of the tub. In most instances the tortoise would right itself, but sometimes tortoises would have to be righted during morning feedings. The only mortality encountered in two years of captivity occurred when a tortoise flipped over underneath its basking lamp and overheated. To reduce basking lamp mortality, an additional wellness check may be necessary in the afternoon.

How captive-reared hatchlings are released into the wild may need careful consideration with respect to the habitat individuals are released into. When releasing translocated adult tortoises, soft releases where tortoises are penned for up to 12 months can increase site fidelity and survival by discouraging long distance roaming (Tuberville et al. 2005) and decrease the likelihood of predation and road mortality. With head-started tortoises this technique may be unnecessary, as their small size limits them from roaming long distances. Also, in the case of our two year old tortoises, most established burrows within seven days of being transferred to our acclimation pens and less than three days at the release sites. A drawback of soft releases, which was experienced at the Hillsdale site, is that they concentrate individuals in a small area, making them more vulnerable to mass predation. Despite all of the juveniles having dug burrows, half of the juveniles at Hillsdale were predated by a single domestic dog within a day of the enclosures being removed. An alternative to the soft release is a hard release, where juveniles are directly released at the burrows from which they were collected as eggs. This technique would eliminate concentrating tortoises in a few enclosures, instead scattering smaller clutch groups back to their respective burrows of egg origin. This should reduce the likelihood of a mass predation event by a single predator, and there would not be a fenced structure to draw the unwanted attention of potential predators and humans.

Our behavior and growth research required the tortoises to be kept in captivity for two years. With the sizes reached after just one year in captivity, it may not be necessary to keep them any longer than one year. If the objective of the project is to overcome the 90% juvenile/hatchling mortality rate found in first year juveniles and/or head-starting a larger quantity of individuals, then retaining juveniles for one year may be sufficient. One of us (JL) is currently running a head-start program at Camp Shelby and will be releasing one-year old *G. polyphemus* in 2016 that were raised using this protocol. By captive rearing indoors, tortoises can attain a large size in a relatively short period of time, as they gain at least an extra five months (November–March) of foraging and growth over wild *G. polyphemus* and individuals head-started in outdoor enclosures. The increased size reduces the chance of predation by smaller predators and can decrease the time required to reach sexual maturity since sexual maturity depends on size rather than age (Iverson 1980; Landers et al. 1980). At the time of release, the two-year old captive tortoises in the present study were equal in size to 5–7 year old wild juveniles at Camp Shelby (Hinderliter and Lee, unpubl. data), which suggests the time required to reach sexual maturity could be reduced by as much as five years. Additionally, although outdoor enclosures may offer protection from many predators, pesticides have to be applied to control fire ants, and some predators still manage to get into the enclosures (e.g., a juvenile *Crotalus adamanteus* found in an outdoor enclosure at Camp Shelby). The Camp Shelby enclosures also required yearly prescribed burning of the vegetation to maintain suitable groundcover for foraging and for sustaining an open understory. The risks of burning the enclosure vegetation not only increased the potential for wildfires outside the enclosure and enclosure damage, but also increased the risk of tortoise fire mortality. Exposure to excessive heat, cold, and drought can also increase mortality in outdoor head-start enclosures.

In conclusion, our captive rearing protocol was able to produce larger juveniles with the ability to build sufficient burrows and promoted juvenile survival in the wild. Around Camp Shelby, wild hatchlings were often observed seeking shelter under leaves, logs, or in shallow pallet burrows that offered limited protection. All of the released captive-reared two-year-old tortoises were able to dig burrows within two days at the Camp Shelby site. This suggests that larger captive tortoises may be more adept at digging burrows deep enough to protect themselves from extreme temperatures, predators and wildfires, in contrast to recent hatchlings which may be unable to dig quality burrows (especially in soils with a high clay content). Wild hatchling burrows are often found beneath clumps of grass, logs and woody debris, which offer little protection from extreme temperatures, fires and predators. If feral dogs and coyotes are

present, only adult burrows appear to be deep enough to escape predation.

Acknowledgments.—Funding for this study was provided by the U.S. Army Corps of Engineers-ERDC-CERL, contract #W9132T-06-2-0021, the National Science Foundation GK-12 program "Connections in the Classroom: Molecules to Muscles," award #0947944 to USM and the Gopher Tortoise Council's J. Larry Landers Student Research Award. This work was conducted under a Mississippi Department of Wildlife, Fisheries, and Parks Scientific Collecting Permit, and USM IACUC protocol #09051403. Transmitters were purchased by the Nature Conservancy's Camp Shelby Field Office, with funds provided by the Mississippi Army National Guard. We thank M. S. DeVries, E. Holbrook, A. Getz, M. Duckworth, K. Gentry, J. Lamb, and M. Winters for assistance with field work, hatchling care, and good advice.

HERPETOCULTURE NOTES

ANURA — FROGS

***RANA SYLVATICA* (Wood Frog). CLUTCH SIZE MEASUREMENT.** Obtaining total counts of eggs or larvae within ranid egg masses can be challenging due to the three-dimensional structure of egg masses and high numbers of eggs and larvae. Nevertheless, herpetologists are occasionally faced with this daunting task when, for example, determining annual female reproductive output or the proportion of fertilized eggs per mating. Several methods are currently used to count exact numbers of eggs and larvae within ranid egg masses, each suitable for different applications (Browne and Zippel 2007. ILAR J 48:214–234). The Displacement method provides estimates (but not exact counts) of total egg numbers and cannot be used to count larvae. The Image Analysis and Direct Counting methods can provide exact counts of both eggs and larvae but require chemical egg gel dissociation and can be very tedious (e.g., hand-counting larvae dropped from the tip of a pipette). Finally, "flattening" methods have also been used for ambystomatid and ranid egg masses, which involve photographing or counting egg masses that are pressed between gridded glass plates (Harris 1980. Copeia 1980:719–722) or food storage containers (Karraker 2007. Herpetol. Rev. 38:46–48); however, the grid lines themselves can obscure some eggs or embryos. In addition, "flattening" methods cannot be used to count larvae.

Here, I describe an alternative method of counting *Rana sylvatica* eggs and larvae that does not involve egg gel dissociation or a gridded press. *Rana sylvatica* egg masses may contain up to 2000 eggs, and therefore direct quantification can be challenging. I used white miniature ice cube trays (Cubette Ice Trays 180, China) as a tool to count these large egg masses and hatched larvae. To count eggs and embryos within an egg mass, I cut small sections and gently rolled them over the ice cube tray. By pressing a finger lightly over an egg mass section, eggs can be separated into the ice cube tray's cells and viewed as a single layer. Each cell of the tray held up to seven eggs. Eggs were easily visible (Fig. 1), which facilitated rapid counting using a mechanical tally counter. Alternatively, eggs in the ice cube tray can be photographed and digitally counted using ImageJ. The ice cube tray method eliminates the problems associated with grid lines and does not require chemical egg gel dissociation to spread the eggs in a single layer. The contrast between the dark embryos and white tray also permits the approximate staging of embryos, with or without a hand lens.

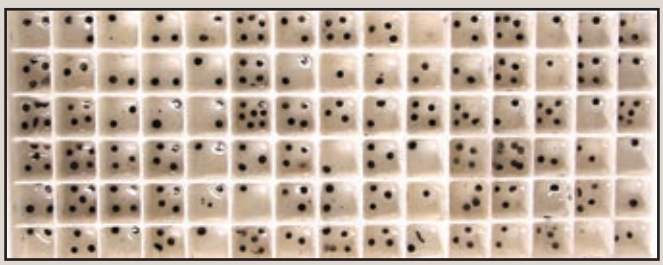

FIG. 1. *Rana sylvatica* eggs prepared for counting using the ice cube tray method.

The ice cube tray method can also be used to rapidly count larvae. *Rana sylvatica* larvae were distributed among the cells of the tray using a plastic disposable pipette with the tip widened or larvae were gently poured from a small specimen cup. Up to six newly hatched larvae can be easily counted per cell. When counting by hand, this method is superior to dropping larvae from a pipette because of the increased accuracy due to the ease of counting, as counts can be performed by counting larvae from left to right in each cell of every row. The ice cube tray method may also be preferred when performing digital larval counts because clumping of larvae can be prevented by adjusting the larval density in individual cells using a pipette, thus providing a more useful photograph for digital analysis. I reared larvae that were counted using this method to metamorphosis in the laboratory; mortality rates for these larvae were low and did not differ from those that were not counted using this method.

All procedures adhered to national and international standards on animal welfare and were compliant with the legal requirements of the United States and the Institutional Guidelines of Penn State University (IACUC permit numbers 42015 and 33346). Animal collection was permitted by the Pennsylvania Game Commission (NC-028-2012) and the Pennsylvania Fish and Boat Commission (Scientific Collector's Permit 483 Type 1).

TESTUDINES — TURTLES

***PYXIS ARACHNOIDES ARACHNOIDES* (Common Spider Tortoise). EGG SHELL REPAIR.** All turtles are oviparous, producing pliable, hard-expansible or brittle egg shells (Ewert 1985. *In* Gans et al. [eds.], Biology of the Reptilia Volume 14: Development A, pp. 75–241. John Wiley and Sons, Inc, New York). The functions of the egg shell are to protect, allow adequate gas and water exchange, and serve as a mineral reservoir for the developing embryo (Palmer and Guillette 1991. *In* Deeming and Ferguson [eds.], Egg Incubation: its Effects on Embryonic Development in Birds and Reptiles, pp. 29–46. Cambridge University Press, Cambridge). In captivity, brittle or hard-shelled reptile eggs can be cracked or broken during oviposition or shortly thereafter. Damaged eggs can be a result of poor nesting sites (Kohler 2005. Incubation of Reptile Eggs. Krieger Publishing Co., Malabar, Florida) or improper handling when retrieving them (Gurley 2003. Keeping and Breeding Freshwater Turtles. Living Art Publishing, Ada, Oklahoma. 300 pp.). Additionally, changes in humidity during incubation can cause an egg to swell and crack (Packard 1994. *In*

Murphy et al. [eds.], Captive Management and Conservation of Amphibians and Reptiles. SSAR, Ithaca, New York; Gurley 2003, *op. cit*).

Several methods to repair reptile egg shells have been used in both zoological institutions and private collections, and discussed openly on internet forums. These include the use of super glue, freezer tape, vinyl patches, paraffin wax, skin glue, Neosporin® (Johnson and Johnson Consumer Inc., New Brunswick, New Jersey), petroleum jelly, clear plastic sandwich bags, and tea bag fabric. Published accounts include the repair of *Morelia viridis* eggs with melted paraffin or the use of a conspecific's egg shell (Maxwell 2005. The More Complete Chondro. ECO Herpetological Publishing and Distribution, Rodeo, New Mexico. 317 pp.), a *Varanus acanthurus brachyurus* egg repaired with a piece of a *V. tristis* egg shell (Adragna and Madden 2009. Biawak 3:144–145), a *V. beccarii* egg sealed with hot wax (Fischer 2012. Biawak 6:79–87), and a *V. prasinus* egg repaired with tissue adhesive (Davis 2014. Biawak 8:39–42). Three *Dracaena guianensis* eggs that ruptured during incubation at the San Diego Zoo were repaired with Tegaderm™ (3M Inc., St. Paul, Minnesota), a transparent clear dressing (R. Walton, pers. comm.). Chelonian eggs have been repaired with surgical tape, Neosporin® (Gurley 2003, *op. cit.*), and plastic wrap (McKeown 1997. Vivarium 8[5]:6–7); *Geochelone nigra* eggs have been repaired successfully using tissue glue (C. Adams, pers. comm.).

FIG. 1. Distended membrane of a *Pixys a. arachnoides* egg prior to repair on 20 April 2015.

FIG. 2. *Pixys a. arachnoides* egg repaired with a section of *Rhacodactylus leachianus* egg shell.

A *Pixys arachnoides arachnoides* at the Smithsonian National Zoological Park laid a single egg in August 2014, followed by a second in September and a third in November of the same year. These eggs were incubated at 28°C in a 2:1 substrate mixture of vermiculite and water by weight. After four weeks, each egg was gradually cooled over a few weeks to 15.5°C where it remained for six weeks before being gradually warmed back up to 28°C for the remainder of its incubation. A large lateral crack in the shell of the third egg was first noticed on 16 March 2015, one month after warming the egg back up to 28°C. The crack continued to expand as the embryo developed, and eventually resulted in the rupture of the shell membrane on 20 April. Fluid began to leak from the egg and blood vessels were apparent in the distended membrane (Fig. 1).

At this time, the egg was repaired using the egg shell from a hatched *Rhacodactylus leachianus*. This shell was soaked in warm water to regain its pliability and disinfected with a 10% bleach solution. Once disinfected and rinsed repeatedly, the shell was soaked in AmQuel® (Novalek Inc., Hayward, California), an ammonia detoxifier, and then thoroughly rinsed again with water. Once dried, a piece of the *R. leachianus* shell was cut with scissors and rubbed with paper towels to remove any loose shell membrane remaining. New Skin Liquid Bandage® (Medtech, Jackson, Wyoming) was applied with a brush to seal the edges of the crack where the egg membrane was not protruding and to attach the *R. leachianus* egg shell directly over the distended membrane (Fig. 2).

Approximately three hours after the repair, the egg began sweating and a strong odor from the New Skin Liquid Bandage® was apparent. For these reasons, the egg incubation container was vented daily; an increase from once a week. Although the egg stopped sweating within 24 h, the smell of the adhesive persisted throughout the remainder of incubation. On 9 June 2015, after 215 days of incubation, the hatchling pipped the egg shell above the repaired section. By the following day the tortoise had made no progress and was manually assist-hatched in order to assess its condition. Upon examination, the tortoise had an open umbilicus, and was kept in the incubator on unbleached paper towels and treated daily with Nolvasan (Chlorhexidine: Fort Dodge Laboratories, Fort Dodge, Iowa) for four days, at which point the plastron had fully healed. This hatchling weighed 10 g; for comparison, the egg laid in September incubated for 244 days and the hatchling weighted 12 g.

Although the origin of this crack is unknown, it is suspected that the egg was either damaged during oviposition or became cracked as a result of some aspect of the incubation method (humidity and/or temperature). This eggshell repair method proved successful in this instance, allowing the continued development of the embryo. The strong odor of the New Skin Liquid Bandage® was concerning and may be avoided by using other forms of adhesive.

SQUAMATA — LIZARDS

***CALOTES VERSICOLOR* (Garden Lizard). AGGRESSION.** Aggressive behavior has been studied in a wide range of animal taxa (Maher and Lott 1995. Anim. Behav. 49:1581–1597; Calsbeek and Sinervo 2002. Oecologia 132:468–477). Aggression in lizards has

been associated with territorial defense (Sheldahl and Martins 2000. Herpetologica 56:469–479), and between males especially during the breeding season (Archer 1988. The Behavioral Biology of Aggression. Cambridge University Press, Cambridge. 272 pp.), and it is evident in different forms such as advertisements using visual displays to physical contact (Martins 1994. *In* Vitt and Pianka [eds.], Lizard Ecology: Historical and Experimental Perspectives, pp. 117–144. Princeton University Press, Princeton, New Jersey). However, in some circumstances, agonistic behavior results in combat between opponents; this behavior can be costly for individuals because of resulting physical injury. The intensity of aggression by territory owners against intruders may vary in accordance with available resources in the habitat for retreat sites from predators, food, and mates (Leuck 1995. Herpetol. Monogr. 9:63–74; Bradbury and Vehrencamp 2011. Principles of Animal Communication, 2nd ed. Sinauer Associates, Sunderland, Massachusetts. 697 pp.). Aggressive behavior in anoles and agamids involves a variety of visual displays, such as headbobs, push-ups, dewlap or gular extensions, and lateral body compression which can advance to physical contact (Jenssen 1977. Amer. Zool. 17:203–215; McMann 2000. Anim. Behav. 59:513–522; Paterson 2002. Herpetologica 58:382–393; Perry et al. 2004. Anim. Behav. 67:37–47; Ammanna et al. 2013. Anim. Biol. 63:47–58). Here, I report for the first time a case of aggressive behavior observed in a female agamid lizard *Calotes versicolor* under captive conditions.

This female was hatched in the laboratory within a group of 15 hatchlings (2 males and 13 females). The hatchlings measured 25.11 ± 0.42 mm SVL ± SE and 44.36 ± 1.12 mm in tail length ± SE) and the body mass ± SE was 470.43 ± 12.53 mg. Sex of the hatchlings was recorded on day 4 by protrusion of the hemipenes as per Harlow (1996. Herpetol. Rev. 27:71–72). The hatchlings were placed in a glass terrarium 60 × 30 × 30 cm (L × W × H) with a 2-mm deep sandy substrate layer and a wooden structure for perching. The hatchlings were provided with food consisting of termites and silk moth larvae. Though the food was supplied *ad libitum*, the hatchlings began dying day by day and some of them were found injured and later died. Five females survived for one month. Among these five, the tails of four were observed becoming shorter in length. A single female in the group was observed chasing and eating the tails of other individuals without killing them.

This dominant female was always found at the top of the perch provided in the cage displaying aggressive behaviors such as push-ups and gular extensions. The dominant female attained maturity (83.48 mm SVL, tail length 141 mm) and was shifted to a new terrarium with an adult male of 115 mm SVL. The female did not attack him nor was any aggression observed. The remaining females with broken tails had the following measurements (SVL/TL, in mm): 70.8/35.66, 82.83/68.25, 74.06/60.64mm.

Tails in lizards are involved in diverse functions such as balance, fat storage, and mating (Ali 1949. Proc. Ind. Acad. Sci. 32:87– 95; Robinson et al. 1970. Mariorana 1977; Vitt et al. 1977. Ecology 58:320–337; Schall and Pianka 1978. Am. Nat. 115:551–566). The directed caudal attacks by the dominant female may have been intended to damage the tails of conspecifics in her group in order to suppress her siblings or as a sort of territory guarding behavior to access the food and basking site in the area provided. Further observations are needed from field studies to determine if such behaviors occur in their natural habitat.

HERPETOLOGICAL HISTORY

Herpetological Review, 2015, 46(4), 547–555.
© 2015 by Society for the Study of Amphibians and Reptiles

History and Fate of a Troubled Reptile Zoo: The Long Island Reptile Museum

For the herpetological enthusiast, New York City and the surrounding area are home to many zoological and educational facilities where live reptiles and amphibians can be viewed on public display. In addition to a suite of museums and nature centers, the region is home to several AZA accredited zoological parks and aquariums with living herpetological collections. With the exception of some of the larger zoos, particularly the Bronx, Central Park, and Staten Island Zoos, most of these facilities have maintained relatively small reptile and amphibian collections comprised predominately of native or common pet-trade species. The Long Island Reptile Museum, a for-profit herpetological exhibition which closed in 2004, was unique in this regard, as it displayed an extensive collection of live reptiles and amphibians that rivaled that of many North American zoos at the time, and saw tens of thousands of visitors from the greater metropolitan area each year. These attributes, coupled with a troubled history that may be unfamiliar to herpetological enthusiasts outside of New York, make the Long Island Reptile Museum a noteworthy facility for fanciers and historians of zoo herpetology.

In this account, I provide a detailed overview of the history and fate of the Long Island Reptile Museum compiled from interviews conducted with former staff members and volunteers, salvaged museum records, published reviews, travelogues, and newspaper reports, and my own personal experiences and reflections as a former reptile keeper of the facility. Documented herein are many of the challenges, hardships, and problems faced by the facility and its staff during its brief existence.

Early History and Specifications

Privately owned and directed by a commercial real estate developer and exotic bird breeder, the Long Island Reptile Museum (hereafter LIRM) opened its doors in July 1995 to much acclaim (Sutton 1997). Strategically situated in Hicksville, Long Island, New York—centrally located in Nassau County (with more than 1 million residents at the time of its opening) and just 18 km from the New York City border, the museum quickly became a popular destination for residents and tourists of the greater New York City area.

ROBERT W. MENDYK
Department of Herpetology, Jacksonville Zoo and Gardens, 370 Zoo Parkway, Jacksonville, Florida 32218, USA
Department of Herpetology, Smithsonian National Zoological Park, 3001 Connecticut Avenue NW, Washington, DC 20008, USA
e-mail: mendykr@jacksonvillezoo.org

Retrofitted inside an existing two-story building once occupied by a five and dime store, the LIRM was immense by zoo reptile house standards, with allegedly 27,000 square feet (2,508 m^2) dedicated to exhibit space. A large fiberglass sculpture of a Jackson's Chameleon (*Trioceros jacksonii*) in the parking lot and the fluorescent green exterior of the building (painted this color in the latter half of its existence) made the museum a familiar and near-unavoidable landmark to passing motorists on Route 107 and travelers on the heavily-commuted Long Island Railroad which ran on elevated tracks adjacent to the building. Inside, the museum featured an extensive exhibit area, a gift shop, a pet shop that sold live reptiles, amphibians, invertebrates, and supplies, and a cafeteria and concessions area that seated around 60 visitors.

The museum was open seven days a week, and welcomed visitors from the general public, schools, scout groups, senior citizen and religious groups, and summer camps. Off-site outreach programs, traveling educational presentations, and local television network appearances were also delivered with regularity. General admission to the museum included a self-guided tour through both floors of exhibits, access to a supervised petting area where visitors could handle select tortoises, lizards, and snakes under the supervision of a docent, and hourly films or live animal presentations in the museum's theater. The museum also became a popular destination for children's birthday parties, with sometimes two or three parties being held simultaneously just to meet the demand on weekends.

Staffing.—Estimates suggest that the LIRM employed close to 100 workers over its history. Excluding part-time guides, birthday party hosts, maintenance staff, and gift shop workers, three to seven keepers typically made up the animal husbandry staff at any given time. Beyond providing daily husbandry and maintaining exhibits, keepers were also responsible for delivering educational programming, museum tours, and public outreach. A variety of volunteers ranging from high school students to adult retirees assisted with diet preparation and various other husbandry-related tasks. On weekends, keepers conducted live animal demonstrations in the theater which occasionally featured venomous reptiles including rattlesnakes, cobras, and helodermatids.

FIG. 2. A large *Varanus salvator* measuring close to 3 m in total length arrived at the LIRM in poor physical condition, obese with extensive callouses on its feet and underbelly (most likely from being maintained on bare concrete). It only survived a few months.

PHOTO BY MARK BAYLESS, COURTESY OF BEN ALLER

FIG. 3. The central petting zoo area of the museum housing *Aldabrachelys gigantea, Geochelone sulcata* and *Iguana iguana.*

Exhibits.—The museum's two floors of exhibit space featured approximately 170 exhibits ranging in size from small 100 × 100 × 100-cm (L × W × H) cubicles to spacious 6 × 4 × 4-m walk-in enclosures. The largest of these exhibits featured professionally fabricated naturalistic elements including rock escarpments, boulders, trees, temple ruins, and waterfalls (Fig. 1). Other large walk-in enclosures were constructed of glass panels and relied instead on natural tree limbs, branches, and rocks as furnishings and decoration. Smaller cubicle enclosures made up the majority of the museum's exhibits, and were arranged in double-tiered rows. Glass aquaria of various dimensions were also incorporated into wall units throughout the first floor's exhibit area.

Some of the larger exhibits on the first floor of the museum featured skylights, although it is unlikely that they were constructed from a UVB-transmissive material. Several small prep rooms with sinks, hoses, and storage spaces were located throughout the museum, and were also where pumps and filtration units for some of the larger exhibits were concealed. Despite the expansive area dedicated to exhibits, a proper quarantine room and off-exhibit holding areas were not incorporated into the facility's design. A makeshift quarantine room was eventually established in a back room on the second floor around 2002, but lacked many of the requirements needed to properly accommodate, quarantine, and acclimatize newly acquired or compromised animals such as running water and wastewater drains.

Collection.—The LIRM spared no expense assembling a diverse and impressive collection of reptiles and amphibians, rivaling that of the nearby Bronx Zoo in terms of both the number of species kept and total specimens displayed. Moreover, with very limited off-exhibit space, the museum probably displayed one of the largest captive collections of reptile and amphibian taxa in the country at the time. With the museum's records likely discarded upon its closure, it is impossible to know the exact number of species and individuals maintained; however, it can be confirmed from salvaged personal records, photographs, and recollections from former keepers and volunteers that at least 224 species of reptile (representing 35 families; Table 1) and 38 species of amphibian (representing 14 families; Table 2) were maintained between 1995 and 2004.

Varanid lizards made up an important component of the collection, with a total of 27 species displayed over the museum's history. Noteworthy specimens included a melanistic form of *Varanus salvator*, *V. varius, V. cumingi*, *V. bengalensis, V. prasinus,* and *V. macraei*, as well as a large *V. salvator* that measured close to 3 m in total length (Fig. 2). The LIRM was also one of the first facilities in the United States to display *V. melinus* and *V. yuwonoi* in captivity following their formal descriptions in the late 1990s. Other noteworthy lizard taxa included *Ctenosaura conspicuosa, Sauromalus varius, Dracaena guianensis, Shinisaurus crocodilurus, Tiliqua rugosa, Cyclura cornuta, C. nubila*, and *C. nubila* × *lewisi* and *C. lewisi* × *nubila caymanensis* hybrids.

Typical of most public reptile exhibits, several large constrictors were prominently displayed including a five-meter long *Eunectes murinus* and several large *Python bivittatus* and *Malayopython reticulatus. Python molurus, Malayopython timorensis, Morelia boeleni, M. amethestina*, and several other pythonids (23 species total) and boids (16 species total) were also kept, as well as at least 13 species of colubrids, most notably *Drymarchon couperi.*

Two adult male *Aldabrachelys gigantea* weighing over 90 kg each were housed together with several adult *Geochelone sulcata, Stigmochelys pardalis,* and occasionally *Iguana iguana* in an open pit enclosure in the museum's central petting area (Fig. 3). Several smaller tortoises including *Chelonoidis petersi, C. carbonaria,* and *C. denticulata* were also displayed in various exhibits. As many as 20–30 aquatic turtles representing several native and exotic species were housed together in a large waterfall-fed pond adjacent to the venomous snake collection towards the exit of the exhibit hall.

A fairly large venomous collection included both venomous lizard species (*Heloderma suspectum* and *H. horridum horridum*) as well as several elapids and viperids including, but not limited to *Ophiophagus hannah* (including a 4.5-m individual), *Naja sumatrana, N. haje, N. melanoleuca, N. kaouthia* (including an albino specimen), *Dendroaspis angusticeps, Bitis gabonica, B. arietans, Atheris squamiger, Vipera palaestinae, Bothriechis schlegelii, Agkistrodon piscivorous, A. contortrix*, and at least four species of rattlesnakes: *Crotalus horridus, C. atrox, C. adamanteus,* and *Sistrurus miliarius.*

Four species of crocodilian were displayed, including an adult breeding pair of *Alligator mississippiensis*, as well as *Caiman crocodylus, Paleosuchus palpebrosus,* and *P. trigonautus.*

Dendrobatids (*Dendrobates, Phyllobates, Epipedobates*) were commonly displayed, as were several other terrestrial (e.g., *Mantella* spp., *Discophus guineti, Pyxicephalus adspersus, Ceratoph-*

rys spp.), aquatic (e.g., *Pipa pipa*), and arboreal (e.g., *Hyla* spp., *Agalychnis callidryas*) anurans. Although a few species were kept, caudates were poorly represented in the collection.

The museum regularly purchased rare and unusual specimens from reptile dealers, breeders, and private collectors, whereas more common pet trade species such as *Iguana iguana*, *Trachemys scripta elegans*, *Geochelone sulcata*, *Boa constrictor imperator*, and *V. niloticus* were frequently acquired through donations or the surrendering of unwanted pets to the museum. Occasionally, some less-common species would get donated, particularly Asian box turtles of the genus *Cuora* (*C. amboinensis*, *C. flavormarginata*, and *C. galbinifrons*). While unwanted pet reptiles, particularly iguanas, Red-eared Sliders, and Boa Constrictors were sometimes abandoned in boxes on the doorstep of the museum at night, even in mid-winter, the museum received the majority of these animals by accepting them with an "adoption fee" upwards of US $150 depending on the species. At times, as many as 10 *I. iguana* were surrendered to the museum inside a month; at the behest of the owner, animals were rarely rejected or turned away.

In addition to reptiles and amphibians, the LIRM also maintained a large collection of live exotic insects and arachnids up until around 2001, when they were replaced with static displays of dinosaur and other extinct reptile fossils.

Captive breeding.—Several reptile species were successfully reproduced at the LIRM, although repeat occurrences were uncommon. Lizard taxa bred on-site included *Rhacodactylus leachianus*, *Shinisaurus crocodilurus*, *Physignathus cocincinus*, *Gehyra vorax*, *Chamaeleo calyptratus*, *Trioceros jacksonii*, *Eublepharus macularis*, *Tiliqua gigas*, and *Pogona vitticeps*. The museum may have been the first facility to receive eggs from *V. melinus* in 1999, although no live hatchlings resulted. Viable eggs were also produced by *Hydrosaurus weberi* in 2002, but were discovered by keepers after they had been destroyed by ants. According to exhibit signage, the museum claimed to have been the first facility to breed *R. leachianus* in captivity in 1998; however, the species had been bred more than a decade earlier by the Dallas Zoo in the mid to late 1980s (J. Murphy, pers. comm.). Offspring were produced from several boas and pythons including *B. constrictor imperator*, *P. regius*, and *Epicrates cenchria*. Chelonians bred onsite included *Cuora flavomarginata*, *Chelydra serpentina*, and *G. sulcata*. Although eggs had been received, it is unclear if *Alligator mississippiensis* was successfully hatched at the museum.

Troubled History

To say that the Long Island Reptile Museum experienced its share of problems over its brief history is perhaps a gross understatement. Many issues relating to the LIRM's directorship and financial support, flawed exhibit design, and inability to retain experienced staff affected the health and welfare of its captives, and ultimately contributed to the demise of the facility after just nine years of operation.

High staff turnover.—The museum experienced difficulty maintaining a consistent and qualified keeper staff. Although several qualified and experienced keepers were employed by the LIRM at various times, the bulk of the museum's animal keepers were recent high school graduates or college students with limited experience with captive reptiles or knowledge of their biology; in many cases, keepers were hired out of nepotism by the museum's owner. Low wages, inconsistent paydays and frustrating work conditions (see below) led to high turnover among staff, especially animal keepers. When experienced individuals did come along, they often did not last long. By default, novice keepers were sometimes left in charge of caring for rare or sensitive species, as well as venomous reptiles, large constrictors, monitor lizards, and crocodilians during "in between" periods without experienced keeper staff. High turnover also contributed to generally poor and inconsistent husbandry and accession records.

Exhibit design.—Flawed exhibit design and construction at the LIRM directly impacted keepers' abilities to properly care for specimens and service their enclosures. Little consideration of reptilian and amphibian biology appeared to have been taken into account in their design, leading to various health and welfare issues. For example, basking lights and other heat-emitting fixtures were usually positioned at great distances from any potential basking surface, making it difficult or impossible for some captives to access appropriate temperatures for thermoregulation. Similarly, ultraviolet light fixtures, when offered, were also installed at distances too great for animals to receive any benefit from them. During colder autumn and winter months, substantial heat was lost to the large surface areas of the skylights in some of the larger exhibits, making it difficult to maintain appropriate thermal gradients inside. Open screen tops on most enclosures facilitated strong diffusion gradients and air flow, causing environmental conditions inside exhibits to equalize with the rest of the building. This created difficulties maintaining appropriate temperatures and humidity levels within enclosures, especially during the cold, dry winters of New York; inadequate humidity levels led to chronic dehydration in many species, and eventually gout in some cases (e.g., *V. varius*, *Uromastyx aegyptia*).

Without an appropriate quarantine room or facility, the practice of accepting unwanted pet reptiles without proper veterinary screening and quarantine led to the transmission of parasites and pathogens to the collection. Snake mites (*Ophionyssus natricis*) were a regular scourge, and in 2003, an unidentified ulcerative dermatitis that was suspected of being introduced to the collection via a surrendered pet *Iguana iguana* spread through several herbivorous iguanid and agamid lizards including a *Cyclura nubila* × *lewisi* hybrid, *C. cornuta*, several *I. iguana*, a *Ctenosaura similis*, and a *Uromastyx aegyptia*. Stomatitis and upper respiratory tract infections were commonly encountered in larger constrictor species. In 2002, several keepers simultaneously became ill and were suspected of contracting giardiasis through contact with contaminated aquatic turtle water; *Cyclemys dentata* in the collection later tested positive for *Giardia*.

Many exhibits at the LIRM featured drainage plumbing. While pools in some of the larger enclosures featured their own direct drainage lines, smaller cubicle exhibits shared drainage plumbing, allowing wastewater from adjacent exhibits to occasionally back up into neighboring enclosures. This posed threats of cross-contamination and facilitated the spread of pathogens, particularly among aquatic and semi-aquatic turtles. Additionally, the generally undersized drain lines in both types of exhibits were incapable of handling large waste products or substrate particles, resulting in frequent clogs and breakage. Several drains eventually became unusable due to impenetrable clogs, and waste water had to be flushed out manually with siphons or sump pumps.

The unusual layout of exhibits throughout the museum also presented challenges for maintenance and accessibility. Some of the entranceways to larger walk-in enclosures were too narrow to

allow for garbage cans, ladders and other equipment needed for cleaning and regular maintenance. Several walk-in exhibits were accessible only through other exhibits; in some cases requiring keepers to walk through two other exhibits to access a terminal enclosure. This presented safety issues for keepers when these exhibits housed large varanids or constrictors, as well as risks of cross-contamination between exhibits.

Unlike most zoos that utilize rear-access doors for their reptile and amphibian exhibits which prevent the public from coming into contact with animals and potential zoonotic agents, most of the exhibits at the LIRM were designed to be front-opening, with the public viewing windows doubling as access doors. This space-saving design also included the museum's venomous snake enclosures; their front-opening design and location just before the exit of the museum presented challenges for servicing enclosures during visitor hours and also posed potential safety and security risks for the general public.

Financial support.—Although significant, the effects of staff turnover and poorly designed exhibits paled in comparison to the problems and hardships associated with the museum owner's reluctance or inability to adequately fund the facility. In a telling premonition, monetary issues were apparent before the museum opened to the public, with various contractors, construction crews and exhibit builders walking out on the job due to nonpayment. There were also issues with paying utility companies; on one occasion during the winter before the museum officially opened, the building's heat was shut off due to nonpayment, resulting in the deaths of several animals from hypothermia. As a temporary solution, electric space heaters were placed inside exhibits to keep their inhabitants warm during periods without natural gas service for heat (Fig. 4). Payment issues with electrical and heating utilities continued throughout the museum's history (see below).

Insufficient funding took a direct hit on keepers' abilities to care for animals properly. Although not a problem initially, funding for animal diets became scarce, and keepers were eventually pressured to come up with alternative ways of feeding the collection which included asking local supermarkets for handouts of the previous day's wilted or expired produce and obtaining live rodents for free through local research laboratories. Limited funding also affected the ability to purchase new materials and equipment such as mulch, sand, and other substrates, heating and lighting fixtures, handling equipment and maintenance supplies. Fluorescent UV lamps were often used beyond their intended lifespans, to where they were probably no longer emitting beneficial UV-B wavelengths.

Veterinary practices began refusing to see animals from the LIRM due to nonpayment or simply the museum owner's reputation for nonpayment. In fact, over the course of just nine years, the LIRM went through around a dozen local veterinary practices, including all of the experienced reptile veterinarians on Long Island. The inability to receive veterinary support when needed, especially towards the end of the museum's operation, further limited keepers' options when it came to treating sick or injured animals in the collection. Similarly, given their expense, necropsies were rarely performed to establish a cause for death, making it difficult for keepers to learn from these experiences.

The museum's owner continued to accept unwanted pet reptiles even if there was not sufficient space to accommodate them, in an effort to collect the accompanying "adoption fee." Curiously, when the museum became overwhelmed with surrendered iguanas, the owner would arrange shipments to dealers in Florida, who purportedly paid US $10–15 per iguana. It is difficult to imagine why anyone would pay money for large and particularly intractable iguanas (many of these animals were not tame or tolerant of human interaction) when thousands sit awaiting adoption in rescue groups throughout the country or roam free in southern Florida. Although their true fates were never revealed, some keepers suspected that they were being sold to food markets.

Investigation by the Turtle Trust.—Alerted to the conditions present at the LIRM, members from the UK-based Tortoise Trust visited the museum in December 2000 and prepared an extensive investigative report detailing the problems and inadequacies observed at the facility as well as recommendations for their remedy (Highfield and Gill 2000). Among their findings, Highfield and Gill (2000) called special attention to the quality of care being provided, the museum's educational value, and the overall conservation message of the facility. In addition to several of the issues hitherto discussed including overcrowding, cross-contagion, mites, and the use of open-topped enclosures which made maintaining appropriate climatic conditions difficult, Highfield and Gill (2000) noted outdated enclosure designs, the unnecessary mixing of unrelated species, inadequate UV exposure, and metabolic bone disease among several tortoises and iguanas in the collection (though these were likely specimens surrendered as adults by pet owners that were already afflicted). The educational focus of the museum was questioned since the conditions on display did not illustrate to the public what they considered to be proper reptile and amphibian husbandry. Also criticized was the conservation message of the facility, since many wild-caught reptiles and amphibians were offered for sale in the museum's pet shop, as well as several species that are poorly suited for private collections including *Geochelone sulcata*, *Python bivitattus*, *Iguana iguana,* and *Varanus salvator*. Similar concerns about the condition of the facility and its husbandry were raised by Harris (2002) following a herpetological society visit to the museum in 2002.

Interestingly, the same conditions and inadequacies highlighted by Highfield and Gill (2000) and Harris (2002) went largely unnoticed or dismissed by the general public, including many reptile hobbyists. Herpetological enthusiasts frequently visited the museum from all over the United States, yet few noticed or raised concerns about its conditions; to the contrary,

many offered their compliments and some even inquired about employment opportunities. An article appearing in *Reptile and Amphibian Hobbyist* magazine around the same time as Highfield and Gill's (2000) investigative report praised the facility and the work that it was doing (Labenda 2000). This would suggest that many reptile and amphibian hobbyists are not familiar with sound husbandry practices or able to recognize signs of impaired animal health and welfare, which raises concerns about the quality of information available to the general pet reptile keeping community and the resulting standards of care they may be providing in their own collections.

Thefts and escapes.—Given the rarity of many specimens in the collection and the poor construction of some of the museum's exhibits, animals were occasionally targeted and stolen from the LIRM by visitors, burglars, and possibly even employees and volunteers. Species stolen from the museum included *Varanus bengalensis, V. prasinus, Rhacodactylus leachianus, Sanzinia madagascariensis, Shinisaurus crocodilurus,* and *Heloderma suspectum*; some, but not all were later recovered by law enforcement officials (Sutton 1996; Lenkowitz 2002; Raferty 2002).

Snake and lizard escapes were not uncommon at the LIRM, with some animals never recovered. Among the most notable escapes were a *Naja kaouthia* that escaped into the floorboards beneath the theater's stage, a five-meter long *Eunectes murinus* that I almost stepped on in a dark hallway one morning after it had escaped from its enclosure the night before when a keeper failed to lock its exhibit door, and a *Varanus melinus* that was regularly spotted throughout the museum, even basking in morning sunlight filtered through the building's skylights, but evaded capture for several weeks. Additionally, like many other zoo reptile buildings, the museum's exhibit area and prep rooms were home to a sizeable breeding population of escaped (or intentionally released?) Tokay Geckos (*Gekko gekko)* which thrived on loose feeder insects and resident cockroaches. Nighttime herping forays for geckos and their eggs became a popular pastime of museum staff and volunteers.

Snakebite.—Emergency responders were called to the museum on 28 December 1997 in response to its first and only venomous snakebite (Crowley 1997; Gearty 1997; McFadden 1997; Miller et al. 1997). A 24-year old keeper was bitten on the hand and envenomated by a 1.2-m long *Bitis gabonica* as he reached into its enclosure to retrieve a water bowl by hand. The victim, who had allegedly been working at the museum for around two years, was airlifted by helicopter to Jacobi Medical Center in the Bronx, where he underwent a fasciotomy and required several vials of antivenom procured by the Bronx Zoo's herpetology department. The keeper eventually recovered from the bite, but never regained full use of his hand. As a result of these injuries, he was later awarded US $1.6 million in damages by a Nassau County Supreme Court referee in 2003 (Anonymous 2003). It is unclear, however, if such a payment was ever received by the victim.

CLOSURE

By 2002, the LIRM had fallen into a state of disrepair, with very little funding available to properly maintain its collection, pay

its employees, and cover basic operational expenses. Faced with even less support from the owner, some keepers began meeting with local authorities from the Nassau County Society for the Prevention of Cruelty to Animals (SPCA) chapter and other rescue organizations, seeking assistance with removing animals in need of veterinary care and getting the museum closed. Despite these talks and knowledge of the museum's conditions by the Nassau County SPCA (Healy 2003), nothing was accomplished and conditions continued to persist for another two years. Keepers were able to convince the owner to voluntarily release some turtles to local rescue groups in 2003; many of these animals required treatment for flagellates (*Giardia* sp. and *Entamoeba* sp.) and nematodes (*Capillaria* sp.). It was also later discovered that during this time a museum volunteer had been working as an undercover operative for an animal rights group and was secretly taking detailed notes and photographs of the museum's conditions, the owner's activities and whereabouts, and the work of its keepers, although this had no apparent effect on the closure of the museum or actions taken against it.

Ironically, the LIRM was forced to close its doors to the public on 29 October 2004 by county officials not because of animal welfare concerns, but because of US $140,000 worth of building and fire code violations (Melago 2004a). After losing heat and electricity to the building several days later due to nonpayment, a small army of volunteers led by the Suffolk County SPCA and representing various agencies, organizations, and rescue groups including Turtlehomes.org and the International Fauna Society (IFS) descended upon the LIRM the evening of 2 November 2004 to remove its living inhabitants as temperatures rapidly dropped to 10°C inside the building (Melago 2004c,d; Winzelberg 2004). Due to a general lack of organization and oversight, several animals mysteriously disappeared from the premises that night without ever being inventoried. The 182 animals that were officially seized were distributed among several rescue groups in the tri-state area for temporary holding, with the majority of animals going to the IFS headquarters in Hauppauge, New York. When it was declared that the owner of the LIRM would not be taking the animals back, some were retained by the IFS for display at its short-lived Serpentarium in Riverhead, New York; others were adopted out or transferred to rescue organizations, and some of the more valuable specimens, including an adult pair of *Varanus cumingi*, were purportedly sold to the public. Many of the animals seized from the museum were in poor physical condition, requiring extensive veterinary treatment or euthanasia.

Coincidentally, the museum's closure occurred just as its owner was in the process of developing a new, floating reptile zoo and aquarium in New York City that was to be permanently docked at South Street Seaport, a popular tourist destination in lower Manhattan. Architectural blueprints had already been drafted and construction of the facility had begun aboard the Cone Johnson, a decommissioned 72-m long ferry purchased from Galveston, Texas (Stewart 2003). Closure of the museum on Long Island and the negative publicity it generated, as well as the owner's citation for misdemeanor animal neglect (Melago 2004b), essentially sealed the fate of this floating facility before it could come to fruition.

The building housing the LIRM was razed the following year and replaced with a retail shopping center.

Discussion

Missed Opportunities for Research.—With such an extensive living collection that included many rare and poorly studied taxa, it is unfortunate that nothing was contributed by the museum's staff to help advance understanding of their biology or husbandry through captivity-based behavioral research or the publication of keeping and breeding reports. For example, captive reproduction occurred in several species at the LIRM that had rarely been bred at the time (e.g., *Rhacodactylus leachianus* and *Shinisaurus crocodilurus*); in these cases, the museum missed out on contributing valuable information to what was then known about their biology, husbandry, and reproduction. Similarly, the museum also missed out on contributing case reports describing novel or unusual health issues and diseases such as the ulcerative dermatitis hitherto discussed as well as an unidentified viral infection that affected the museum's *Aldabrachelys gigantea*.

Financial Sustainability.—Many larger, accredited zoological institutions rely heavily on governmental subsidies, grants, bonds, endowments, corporate beneficiaries, and private donors for covering large parts of their operational expenses; others have branched out to include other revenue streams such as exhibit design to help cover these expenses (e.g., Peeling 2014). As a small for-profit entity, the LIRM relied solely on revenue generated from admission sales, educational programs, and birthday parties to cover its overhead. While the financial mismanagement and business practices of the museum's owner undoubtedly played the greatest contributing role in the facility's demise, it is difficult to imagine how the LIRM could have ever been financially sustainable even if it had been managed effectively. The sheer size of the facility and its associated operational expenses, particularly its monthly electrical usage and heating and cooling costs, should have rendered it cost-prohibitive from its inception. A smaller facility with a smaller collection could have conceivably met the same goals of the LIRM and reached the same number of visitors, while maintaining a much lower operational overhead.

Preventing similar occurrences.—One of the most perplexing questions surrounding the history of the Long Island Reptile Museum is how could it have been allowed to persist for as long as it did given the many problems and animal welfare issues it experienced throughout its history? Where were the authorities? More importantly, what can be learned from the LIRM to prevent similar situations in the future?

First, although volunteer-based animal law enforcement agencies such as the Nassau County SPCA may be highly skilled at pinpointing and addressing welfare concerns among companion animals and domestic livestock, they do not appear as competent or knowledgeable in matters relating to reptiles and amphibians. This may stem from unfamiliarity with reptilian and amphibian biology and husbandry, a general unwillingness to pursue cases involving these taxa, or even a lack of authoritative power regarding the seizure of animals from privately-owned facilities. This latter point may explain why the Suffolk County SPCA (an actual law-enforcement entity) was involved in the LIRM'S seizure rather than the local, volunteer-based Nassau County chapter. Increased training and educational opportunities supported by zoos, federal and state wildlife agencies, and non-profit organizations can help better equip law enforcement officials and related agencies with the knowledge and skills needed for identifying and addressing concerns of poor reptile and amphibian husbandry and welfare.

Second, with the exception of annual license renewals for displaying venomous reptiles and crocodilians through New York State's Department of Environmental Conservation (DEC), the LIRM was exempt from oversight and regulation by

FIG. 5. A young keeper (RWM) experiments with constructing a rock background for a refurbished lizard exhibit.

governmental agencies that monitor or regulate the keeping of certain wildlife groups in captivity such as the United States Fish and Wildlife Service (USFWS) and the United States Department of Agriculture (USDA). Although all facilities publicly displaying live mammals in the U.S. must be licensed as exhibitors through the USDA's Animal and Plant Health Inspection Service (APHIS), which requires adherence to standardized husbandry practices and site inspections, no such regulatory system is in place for facilities displaying live reptiles and amphibians. Additionally, although many zoos and aquariums in North America belong to the AZA, a non-governmental organization that sets rigorous standards for animal husbandry, welfare, and education among its accredited member institutions, membership to the AZA is voluntary, and facilities displaying live animals are not required to join. Thus, problematic herpetological facilities like the LIRM can operate outside the jurisdiction of regulatory governmental agencies and oversight of zoo organizations, where suboptimal husbandry and veterinary care can occur and persist.

While no such system is currently in place for reptiles and amphibians in the USA and no immediate plans to include these taxa have been voiced by the USDA, future inclusion of reptiles and amphibians into APHIS could provide a way in which facilities operating outside the oversight of the AZA like the LIRM can be held accountable and compliant to acceptable standards of herpetological husbandry and welfare. Whether the USDA is logistically capable of launching such a program and effectively regulating herpetological facilities remains to be seen, however, and many zoo curators and registrars would probably argue against such an initiative given the added strain and bureaucracy that it would inevitably create.

Was the Long Island Reptile Museum Valuable to Society?—It might be difficult to look past the many problems and issues experienced by the Long Island Reptile Museum to see any positive aspects, and in reality, an entire book could, and perhaps should be dedicated to the many details of its troubled history and fate. However, in spite of its problems and brief longevity, the LIRM did make three important contributions to society.

First, the Long Island Reptile Museum provided opportunities to many budding herpetologists and naturalists seeking to gain experience working with reptiles and amphibians in captivity. Today, entry-level reptile keeper positions at most AZA accredited zoos in the United States require a bachelor's degree in the biological sciences as well as some level of prior experience working with reptiles and amphibians in a captive setting. First-hand experience gained through private facilities like the LIRM as well as museums and nature centers have prepared individuals for future careers in zoo biology, veterinary medicine or academia, and many prominent zoo biologists have undoubtedly began their careers at smaller, non-accredited facilities. Several former keepers and volunteers of the LIRM including myself have used the experience as a jumping off point to successful careers in zoo biology, veterinary medicine, environmental law, science education, and zoological exhibit design.

Working under such stressful conditions at the LIRM did end up benefiting keepers and volunteers in ways they may not have noticed or appreciated at the time. From my own experience and based on feedback from other former keepers, these suboptimal working conditions contributed to faster learning curves than those we've experienced under more favorable conditions at other zoological facilities. Without in-house maintenance, plumbing, electrical, carpentry, pest control, or exhibit departments to call upon for emergencies and repairs, keepers were forced to learn a myriad of skills and trades on the job through trial and error, teamwork, and collaboration. Solving such problems on a regular basis gave rise to ingenuity and creativity in ways keepers at other zoological institutions might not typically experience or utilize in the day-to-day performance of their jobs. Today, many former keepers of the LIRM are familiar with most areas of general construction and experienced in the fabrication and repair of zoological exhibits (Fig. 5).

Similarly, with very limited husbandry and veterinary support, novice keepers were forced to learn about the biology, health, and medical management of species on their own, by familiarizing themselves with the zoological and veterinary literature and consulting with outside experts. Under unfavorable conditions beyond their control, keepers quickly learned about the individual preferences and tolerances of many reptiles and amphibians as well as their behavioral responses to unnatural social groupings and dominance hierarchies, and suboptimal thermal and hydric conditions. Although far from ideal, these conditions contributed to valuable learning opportunities and unique keeping perspectives that would not have otherwise been possible at other facilities. The experience, knowledge, and know-how gained through working at the LIRM have helped many former keepers succeed and excel at other zoological institutions.

Second, the LIRM played an important role in changing public opinions towards reptiles and amphibians. As some of the most feared and loathed groups of animals on the planet, reptiles and amphibians are frequently misunderstood and misrepresented by the general public, law enforcement officials, politicians, and the media. Zoos and smaller facilities like the LIRM are a necessity for educating people about reptiles and amphibians, while also dispelling fears, myths, and prejudices that can lead to their endangerment in the wild. Given the quantity and breadth of visitors reached through the museum's educational and outreach programs, the LIRM undoubtedly helped further this initiative.

Lastly, and perhaps most importantly, the LIRM was instrumental in inspiring a new generation of herpetologists, naturalists, and wildlife conservationists. For many former keepers, one of the most rewarding aspects of the job was talking with children who returned to the museum with their supportive parents every weekend, who knew the entire collection as well as every minor detail about a species' natural history. It was

gratifying to know that someday these individuals might go on to pursue careers in herpetology or related fields. To further emphasize this final point and conclude this article, I highlight the following experience.

Around 2002, the LIRM was contacted by an 11-year old reptile enthusiast seeking assistance with a proposed project for his elementary school's science fair. As an admirer of snakes and fascinated with snake venoms, the student's ambitious project sought to test and demonstrate, under professional supervision, the effects of rattlesnake venom on human blood. Using just a few droplets of venom collected by keepers from a Pygmy Rattlesnake (*S. miliarius*) in the collection, and petri dishes of fresh blood drawn on-site from the child's father by an accompanying physician, the remarkable platelet-aggregating effect of the venom was demonstrated in real-time and recorded on video by the student. While it is unclear if the student went on to win top prize at his science fair, one can imagine the impact that this experience had on this budding herpetologist's life and career aspirations. Given his age at the time of the experiment, it would not be surprising if this person is now a graduate student on his way to becoming a lead researcher of snake venoms, and perhaps even reading this account.

Acknowledgments.—I thank Lori Green and the many former staff members and volunteers who contributed useful information to this article but who chose to remain anonymous. I am grateful to John Adragna and Ben Aller for sharing images. Finally, I thank Jim Murphy for his support of this project, and Judith Block, Lauren Augustine, and Kyle Miller for helpful comments on earlier drafts of this manuscript.

ROBERT COLVIN (e-mail: Rob.Colvin@tn.gov), and **JAKE YOES**, Tennessee Wildlife Resources Agency, Region I, 200 Lowell Thomas Drive, Jackson, Tennessee 38301, USA (e-mail: jyduck1@hotmail.com).

***AMBYSTOMA TEXANUM* (Small-mouthed Salamander)**. USA: ARKANSAS: Sharp Co.: 5.4 air km W of Ash Flat (36.22245°N, 91.66907°W; WGS 84). 7 March 2014. Charles Foster. Verified by Chris Thigpen. Arkansas State University Museum of Zoology (ASUMZ 32056). New county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville, Arkansas. 421 pp.). This record fills a distributional gap between surrounding counties for this species in northern Arkansas. This specimen was collected under a Scientific Collecting Permit (#020520134) issued to SET by the Arkansas Game and Fish Commission.

CHARLES T. FOSTER (e-mail: charles.foster@smail.astate.edu) and **STANLEY E. TRAUTH,** Department of Biological Sciences, Arkansas State University, P.O. Box 599, State University, Arkansas 72467, USA (e-mail: strauth@astate.edu).

***ANEIDES AENEUS* (Green Salamander)**. USA: NORTH CAROLINA: Buncombe Co.: Private property, Rocky Broad River corridor, 3.4 km airline N town of Bat Cave (35.48°N, 82.28°W; WGS 84). 8 May 2015. Lori A. Williams, Alan D. Cameron, Bill and Jerry McAninch. Verified by Jeffrey C. Beane. North Carolina State Museum of Natural Sciences photo voucher (Accession 13183). New county record (NCSM files; Beane et al. 2010. Amphibians and Reptiles of the Carolinas and Virginia, 2nd ed. University of North Carolina Press, Chapel Hill, 274 pp.; North Carolina Natural Heritage Program 2015. Biotics Database. Department of Environment and Natural Resources, Raleigh, North Carolina). Record represents the northernmost known occurrence in the greater Bat Cave area and on the western side of the Hickory Nut Gorge in North Carolina (Beane et al. 2010, *op. cit.* and NCNHP, *op. cit.*). Closest previous historical records in the state are from private property, Henderson Co., 1.6 km airline S (35.47°N, 82.28°W; WGS 84). Juvenile regenerating entire tail (TL = 41.1 mm, SVL = 37.5 mm) found during visual encounter surveys of rock outcrops.

LORI A. WILLIAMS, North Carolina Wildlife Resources Commission, 177 Mountain Laurel Lane, Fletcher, North Carolina 28732, USA (e-mail: lori.williams@ncwildlife.org); **ALAN D. CAMERON**, 1030 W. Blue Ridge Road, Flat Rock, North Carolina 28731, USA (e-mail: adcamer77@bellsouth.net); **BILL** and **JERRY McANINCH**, P.O. Box 243, Bat Cave, North Carolina 28710, USA.

***EURYCEA GUTTOLINEATA* (Three-lined Salamander)**. USA: ALABAMA: Coosa Co.: 0.16 road km S of Coosa County Road 56 on Coosa County Road 55, in McCutchen Branch just east of road (33.00526°N, 86.36529°W; WGS 84), 186 m elev. 28 April 2015. David Laurencio and Christina M. Holbrook. Verified by Craig Guyer. Auburn University Natural History Museum (AUM 41139). New county record (Mount 1975. Reptiles and Amphibians of Alabama. Auburn University Agricultural Experiment Station, Auburn, Alabama. 347 pp.). Specimen collected under General Scientific Collecting Permit No. 8309, issued by the Alabama Department of Conservation and Natural Resources, Wildlife and Freshwater Fisheries Division.

DAVID LAURENCIO, Auburn University Museum of Natural History, Department of Biological Sciences, 101 Rouse Life Sciences Building, Auburn University, Alabama 36849, USA (e-mail: norops@auburn.edu); **CHRISTINA M. HOLBROOK**, Department of Biological Sciences, 101 Rouse Life Sciences Building, Auburn University, Alabama 36849, USA.

***EURYCEA SOSORUM* (Barton Springs Salamander)**. USA: TEXAS: Travis Co.: Zara Monitoring Well (State Well No. 58-50-705; 30.142235°N, 97.842087°W; WGS 84). 30 July 2015. Collected by Peter Sprouse and Barrett Clark. Verified by Andrew Gluesenkamp. Texas Natural History Collections (TNHC 96003 [Zara 8982; AGG 2172]). Sixth known location for the species, the first time that *E. sosorum* has been collected from a well, and the deepest water depth from which it has been documented (Chippindale 2014. Final Report: Status of newly discovered cave and spring salamanders [*Eurycea*] in southern Travis and northern Hays counties. Report prepared for TPWD. 29 pp.). After checking a bottle trap 212 times between 2010 and 2015, a juvenile *Eurycea sosorum* was collected from a 61-m deep monitoring well intersecting the Edwards Aquifer. The bottle trap was located approximately 58 m below the ground surface, at a water depth of 38 m. The external morphology and coloring of this specimen appears very similar to topotypical Barton Springs Salamanders, including a "shovel-nose," reduced eyes, and long, slender limbs. The specimen exhibited a combination of pigment gaps and high iridophore concentration that is typical of specimens from the type locality (Chippindale et al. 1993. Herpetologica 49:248–259).

All other known localities are springs, except the Blowing Sink Cave site, which is a shallow (0.5 m deep) cave stream located in a passage approximately 70 m below the surface. Chippindale (2014, *op. cit.*) suggests that three sites in Travis Co. (Barton Springs, Cold Springs, and Blowing Sink Cave) and two sites in Hays Co. (Spillar Ranch Springs and Taylor Springs) represent the additional known localities of this species. USFWS Recovery Permit: TE85077A-1.

KRISTA McDERMID (e-mail: krista@zaraenvironmental.com), **PETER SPROUSE** (e-mail: peter@zaraenvironmental.com), and **JEAN KREJCA**, Zara Environmental LLC, 1707 West FM 1626, Manchaca, Texas 78652, USA (e-mail: jean@zaraenvironmental.com).

***NOTOPHTHALMUS PERSTRIATUS* (Striped Newt)** USA: FLORIDA: Jefferson Co.: Dixie Plantation (30.635456°N, 83.678316°W, WGS 84). 3 May 2015. E. Pierson Hill and Kimberly J. Sash. Verified by Kenneth L. Krysko. Florida Museum of Natural History (FLMNH 175785). New county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final report, Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.). We dipnetted six larvae ranging in size from approximately 2.5–3.0 cm TTL. All were found in 0.5–1 m of water near the edge of a grass-dominated ephemeral pond in fire-maintained upland pine woodlands. To verify the species identity, a single larva was taken into captivity where it was raised to metamorphosis and entered the eft stage during the week of July 27. This specimen partially fills a distributional gap between populations formerly existing in Leon and Wakulla counties and populations along the Suwannee River in northern peninsular Florida. The nearest known population (now extirpated) occurred approximately 45 km to the west in Leon Co. (FLMNH 165018). At present, this record represents one of four known extant populations within the range of the western clade of this rare and declining species.

E. PIERSON HILL, Florida Fish and Wildlife Conservation Commission, 5300 High Bridge Rd., Quincy, Florida 32351, USA (e-mail: Pierson.Hill@MyFWC.com); **KIMBERLY J. SASH**, Tall Timbers Research Station and Land Conservancy, 13093 Henry Beadel Dr., Tallahassee, Florida, 32312, USA (e-mail: ksash@ttrs.org).

***NOTOPHTHALMUS PERSTRIATUS* (Striped Newt)**. USA: FLORIDA: Volusia Co: Merritt Island National Wildlife Refuge (28.8277°N, 80.8288°W; WGS 84). 1 May 2015. Stephanie Weiss. Verified genetically by Eric Hoffman. Florida Museum of Natural History (UF-Herpetology 175884 [color photo]). New county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final report, Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.). Nearest record is ca. 37.5 km SW near Chuluota, Seminole Co., from 1935 (CM 9454). Nearest record along the Atlantic Coast is 103 km NNW at Faver-Dykes State Park, St. Johns Co. Collected one larva while dipnetting an interdunal swale in scrub habitat.

CASTELLÓN**, Florida Fish and Wildlife Conservation Commission, 1105 S.W. Williston Road, Gainesville, Florida 32601, USA.

***NOTOPHTHALMUS VIRIDESCENS* (Eastern Newt)**. USA: INDIANA: Jefferson Co.: Big Oaks National Wildlife Refuge (38.840166°N, 85.427178°W; NAD 83). 7 May 2015. Jason Mirtl, Benjamin Walker, and Joseph Robb. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2015av, photo voucher). This capture provides a new county record for Indiana (Minton 2001. Amphibians and Reptiles of Indiana, 2nd ed., revised. Indiana Academy of Science. vii + 404 pp.).

SARABETH KLUEH-MUNDY (e-mail: sklueh-mundy@dnr.IN.gov) and **JASON MIRTL**, Wildlife Science Unit, Indiana Department of Natural Resources, Division of Fish and Wildlife, 5596 East State Road 46, Bloomington, Indiana 47401, USA; **BENJAMIN WALKER** (e-mail: benjamin_walker@fws.gov) and **JOSEPH ROBB**, Big Oaks and Muscatatuck National Wildlife Refuge Complex, 1661 West JPG Niblo Road, Madison, Indiana 47250, USA (e-mail: joe_robb@fws.gov).

***NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS* (Central Newt)**. USA: ARKANSAS: Cleburne Co.: 0.46 km SE of the intersection of Tylar Road and Center Ridge Road (35.52711°N, 91.84973°W; WGS 84), 180 m elev. 19 June 2015. Thomas J. Belford. Verified by William E. Duellman. The University of Kansas Natural History Museum (KUDA 012449). First county record (Trauth et al. 2004 The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.; Roberts and Irwin 2012. Arkansas Herpetological Atlas 2012, Distributions of Amphibians and Reptiles. Available online at: http://www.herpsofarkansas.com/wiki/uploads/Herp/Atlas/arherpatlas2012_appendix_a.pdf). A single specimen in eft stage was found crossing the road after a brief summer storm. This record fills a distribution gap among White, Independence, Stone, Van Buren, and Faulkner counties.

THOMAS J. BELFORD (e-mail: thomasbelfordiniraq@yahoo.com) and **CHLOE A. BELFORD**, 37 White Oak Cir, Searcy, Arkansas 72143, USA.

***PSEUDOBRANCHUS STRIATUS* (Northern Dwarf Siren)**. USA: FLORIDA: Santa Rosa Co.: Blackwater River (30.64837°N, 87.01146°W; WGS 84). 29 April 2015. Jason H. O'Connor. Verified by Paul Moler. Florida Museum of Natural History (UF 175647). New record from the Blackwater River, second confirmed county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final report, Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.). Six individuals collected in 2002 from the Escambia River drainages expanded the known range 115 km W from the Choctawhatchee River drainage in Walton Co. (Means and Means 2002. Herpetol. Rev. 33[4]:316). This record is 34 km ESE from the Escambia record and partially fills the large gap between that record and the Choctawhatchee record 90 km to the east. Specimen was collected over mucky substrate, using a boat propelled push net in ~ 1.5 m of water.

JASON H. O'CONNOR, Fish and Wildlife Research Institute, Florida Fish and Wildlife Conservation Commission, 8384 Fish Hatchery Road, Holt, Florida 32564, USA; e-mail: Jason.OConnor@MyFWC.com.

***PSEUDOTRITON MONTANUS* (Mud Salamander)**. USA: GEORGIA: Hancock Co.: St. Pauls Church Rd. (33.24679°N, 82.86308°W; WGS 84). 25 May 2015. S. Graham. Verified by John B. Jensen. Sul Ross State University (SRSU 6745–6746). New county record (Jensen et al. 2008. The Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Adult and recent metamorph found under leaf litter in first-order branch draining a gum pond.

Funding for this collection trip was provided by a grant from the Georgia Department of Natural Resources.

SEAN P. GRAHAM, Department of Biology, Geology, and Physical Sciences, Sul Ross State University, Alpine, Texas 793830, USA; e-mail: sean.graham@sulross.edu.

ANURA — FROGS

***ACRIS CREPITANS* (Eastern Cricket Frog)**. USA: ALABAMA: Coosa Co.: 0.16 road km S of Coosa County Road 56 on Coosa County Road 55, in a wetland/pond on west side of road (33.00544°N, 86.36530°W; WGS 84), 186 m elev. 28 April 2015. David Laurencio

and Christina M. Holbrook. Verified by Craig Guyer. Auburn University Natural History Museum (AUM 41142). New county record (Mount 1975. Reptiles and Amphibians of Alabama. Specimen collected under General Scientific Collecting Permit No. 8309, issued by the Alabama Department of Conservation and Natural Resources, Wildlife and Freshwater Fisheries Division.

DAVID LAURENCIO, Auburn University Museum of Natural History, Department of Biological Sciences, 101 Rouse Life Sciences Building, Auburn University, Alabama 36849, USA (e-mail: norops@auburn.edu); **CHRISTINA M. HOLBROOK**, Department of Biological Sciences, 101 Rouse Life Sciences Building, Auburn University, Alabama 36849, USA.

***ANAXYRUS FOWLERI* (Fowler's Toad)**. USA: INDIANA: Tippecanoe Co.: Granville Sand Barrens (40.396903°N, 87.057626°W; WGS 84) 23 August 2015. Zachary Truelock. Verified by Kenneth Krysko. Florida Museum of Natural History (UF-Herpetology 176029, photo voucher). New county record (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. vii + 404 pp.). A single juvenile was found hopping along the ground.

ZACH TRUELOCK, Purdue University, 580 McCutcheon Hall, West Lafayette, Indiana 47907, USA; e-mail: ztrueloc@purdue.edu.

***ARTHROLEPTIS ADELPHUS* (Foulassi Screeching Frog)**. GABON: Ogooué-Ivindo Province: buffer zone of Lopé National Park, Ramba Village (00.3635°S, 11.7872°E; WGS 84), 220 m elev. 5 June 2013. J. G. Larson. Verified by D. C. Blackburn. Museum of Comparative Zoology (MCZ Cryo 2318). Identification was confirmed by mitochondrial data from the 16S rRNA gene (GenBank Accession KT723025). Divergence from verified *A. adelphus* sequences was <2% (Blackburn 2008 Mol. Phylogenet. Evol. 49:806–826). This is the first record of this species in the vicinity of Lopé National Park of Gabon (Christy et al. 2008. Checklist of the Amphibians, Reptiles, Birds, and Mammals of the National Parks of Gabon. Washington, D.C., Smithsonian Institution). It has previously been recorded from Loango and Moukalaba-Doudou national parks. Adjacency to Lopé National Park suggests that this species is also found within park boundaries. This specimen was collected under permits from Centre National de la Recherche Scientifique et Technologique, (CENAREST; AR0013/13), Agence Nationale des Parcs Nationaux (ANPN; AE130014), and Direction de la Faune et de la Chasse (82/DGFAP).

JOANNA G. LARSON, Department of Ecology and Evolutionary Biology, Museum of Zoology, University of Michigan, 1109 Geddes Avenue, Ann Arbor, Michigan 48109, USA (e-mail: jglarson@umich.edu); **BREDA M. ZIMKUS**, Department of Organismic and Evolutionary Biology, Museum of Comparative Zoology, Harvard University, 26 Oxford Street, Cambridge, Massachusetts 02138, USA (e-mail: bzimkus@oeb.harvard.edu).

***CRAUGASTOR AUGUSTI* (Barking Frog)** USA: TEXAS: Brewster Co.: U.S. Hwy 385, 21.3 km N of Marathon (30.33476°N, 103.08096°W; WGS 84). 21 August 2014. S. Graham and C. Kelehear. Verified by Troy Hibbits. Sul Ross State University (SRSU-D 28, digital photo voucher). New county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 447 pp.). There is a previous record for *Craugastor augusti* to the southeast from adjacent Terrell Co., Texas (SRSU-A 119; Joe Chandler Ranch near Dryden; 04-17-1964; SRSU records). However, given that Brewster Co. is larger than the state of Rhode Island, our new record represents a substantial (~ 120 km) range extension to the west for *C. augusti* in this region of Texas.

SEAN P. GRAHAM, Department of Biology, Geology, and Physical Sciences, Sul Ross State University, Alpine, Texas 79832, USA (e-mail: sean.graham@sulross.edu); **SKYLER STEVENS**, Department of Natural Resource Management, Sul Ross State University, Alpine, Texas 79832, USA; **CRYSTAL KELEHEAR,** Smithsonian Tropical Research Institute, Apartado 0843-03092, Balboa, Ancon, Panama (e-mail: crystal.kelehear@hotmail.com).

***DUTTAPHRYNUS STOMATICUS* (Marbled Toad)**. BANGLADESH: RAJSHAHI DIVISION: Naogaon District: Patiamly Village (25.060595°N, 88.440832°E; WGS 84) 25.9 m elev. 1 June 2013. Faysal Ahmad. Verified by Monirul H. Khan. Zoology Museum, Department of Zoology, Jagannath University, Dhaka (P1180109, JnU/Zoo/M/Amp/Pho/2015/0010, photo voucher; adult specimen unnumbered); Zoological Reference Collection, Lee Kong Chian Natural History Museum, National University of Singapore (ZRC [IMG] 1.77, photo voucher). First record for Naogaon District, NW Bangladesh. Previously reported from Chittagong, Syllhet and Khulna Division (Hasan et al. 2014. Amphibians and Reptiles of Bangladesh – A Field Guide. Arannayk Foundation, Dhaka. 191 pp.). From grassland habitat including sandy riverine island and coastal mangroves.

FAYSAL AHMAD (e-mail: faysal.nature@gmail.com) and **SHAYER MAHMOOD IBNEY ALAM**, Department of Zoology, Jagannath University, Dhaka 1100, Bangladesh (e-mail: shayermia@hotmail.com).

***ELEUTHERODACTYLUS CYSTIGNATHOIDES* (Rio Grande Chirping Frog)**. USA: ALABAMA: Mobile Co.: 0.85 road km S of AL 217 (Lott Rd.) on Cayton Rd. (30.79687°N, 88.24260°W; WGS 84). 11 February 2013. Raymond McConnell. Verified by Toby

J. Hibbitts. Auburn University Natural History Museum (AUM 40138–40140). New state record (Mount 1975. Reptiles and Amphibians of Alabama. Auburn University Agricultural Experiment Station, Auburn, Alabama. 347 pp.). To our knowledge, this is the first report of this species in Alabama. This locality extends the species range eastward by 275 km from the nearest location in East Baton Rouge, Louisiana (Boundy and Gregory 2012. Herpetol. Rev. 43:113–114). Specimen collected under General Scientific Collecting Permit No. 8309, issued by the Alabama Department of Conservation and Natural Resources, Wildlife and Freshwater Fisheries Division.

RAYMOND McCONNELL (e-mail: raymondmcconnell@gmail.com) and **TAMARA McCONNELL**, 510 Valley Rd, Chickasaw, Alabama 36611, USA; **CRAIG GUYER** and **DAVID LAURENCIO** (e-mail: norops@auburn.edu), Auburn University Museum of Natural History, Department of Biological Sciences, 101 Rouse Life Sciences Building, Auburn University, Alabama 36849, USA.

***ELEUTHERODACTYLUS CYSTIGNATHOIDES CAMPI* (Rio Grande Chirping Frog)**. USA: TEXAS: Colorado Co.: Zimmerscheidt Road at Brushy Creek (29.806490°N, 96.495880°W; WGS 84), 96 m. elev. 12 April 2015. William L. Farr. Verified by Travis J. LaDuc. Texas Natural History Collections (TNHC 95466). This is the first county record for this introduced species, with previous records for two (Austin to the northeast and Fayette to the northwest) of the five adjacent counties previously documented (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. 3rd ed. Texas A&M University Press, College Station. 477 pp.). Numerous additional calls were heard at this locality and at several other localities in the vicinity, indicating the species is well established in northern Colorado Co. The frog was found out and moving under a bridge at 2309 h. during a light rain.

WILLIAM L. FARR, Houston, Texas 77096, USA (e-mail: williamfarr@sbcglobal.net); **MICHAEL R. J. FORSTNER**, Texas State University, Department of Biology, 601 University Drive, San Marcos, Texas 78666, USA (e-mail: MF@txstate.edu).

***ELEUTHERODACTYLUS CYSTIGNATHOIDES* (=*SYRRHOPHUS CYSTIGNATHOIDES*) (Rio Grande Chirping Frog)**. USA: TEXAS: Bell Co.: Cedar Gap Park in Killeen (31.015196°N, 97.650884°W; WGS 84), 190.8 m elev. 13 May 2015. Ciprenio Magno-naoe, Andrew R. MacLaren, Shawn F. McCracken, and Michael R. J. Forstner. Verified by Toby J. Hibbitts. Texas A&M University, Biodiversity Research and Teaching Collections (TCWC 100343,100344). New county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 447 pp.). This discovery occurs within the previously documented *E. cystignathoides* expansion between Dallas and Travis counties. We suspect expansion of this species will continue northward. Unvouchered records of *E. cystignathoides* from Bell Co. exist at the Texas Natural History Collection, but this specimen represents the first confirmed and published record of *E. cystignathoides* record from the county. The nearest (previously unreported) record is 29 km E (TNHC 84601). This species was heard during anuran call surveys at Cedar Gap Park on Stillhouse Lake. Two adult specimens (21.7 mm and 22.8 mm SUL) were collected. Both specimens were captured while calling near one another among dead trees and brush. Anuran calls were only heard on the north side of the park where rotting, flotsam logs had accumulated. Hays Co.: Rio Vista Park and Crook Park in San Marcos (29.880149°N, 97.933757°W; WGS 84), 176.5 m elev. 27 April 2015. Ciprenio Magno-Naoe, Andrew R. MacLaren, Shawn F. McCracken, and Michael R. J. Forstner. Verified by Toby J. Hibbitts. TCWC 100341, 100342. New county record (Dixon 2013, *op. cit.*). The nearest previously documented record is ca. 22.5 km E in Caldwell Co. (TNHC 89683). The record fills the distributional gap among the surrounding counties of Travis, Caldwell, Guadalupe, and Comal. This species was initially observed on 25 April 2015 during anuran call surveys. Two adult specimens (25.5 mm and 21.5 mm SUL) were collected 27 April 2015. The first individual was captured in a concrete crevice near railroad tracks at Rio Vista Park. The second individual was captured on top of a fallen tree limb in Crook Park, 0.38 km S of Rio Vista. Numerous additional individuals were heard calling at both sites.

Specimens collected under Scientific Permit SPR-0102-191 issued to Michael R. J. Forstner by Texas Parks and Wildlife Department.

***HYLA WRIGHTORUM* (Arizona Treefrog)**. USA: ARIZONA: Cochise Co.: Brown Canyon Ranch (31.475322°N, 110.297749°W; WGS 84). 7 July 2015. Valerie Buxton. Verified by Christopher A. Phillips. Illinois Natural History Survey (INHS 2015aw, photographic voucher). Updated county record (USFWS Species Assessment Form; http://ecos.fws.gov/docs/candidate/assessments/2014/r2/D03S_V02.pdf; 10 July 2015). Multiple males were observed calling from a breeding pond on 7 July 2015 and subsequent dates. These individuals belong to the Huachuca-Canelo distinct population segment. In Arizona, this species has been observed at eight of 13–16 sites within the last two decades, with the majority of these observations noted more than 10 years ago (USFWS Species Assessment Form; *op. cit.*). The current distribution is poorly understood and the species is a candidate for listing under the Endangered Species Act. This record confirms the current distribution of *H. wrightorum* in the Huachuca Mountains.

***INCILIUS NEBULIFER* (Gulf Coast Toad)**. USA: TEXAS: Jim Hogg Co.: FM 1017 S of Hebronville (27.23623°N, 98.65029°; WGS84) 152 m elev. 6 June 2007. Collected by Carl J. Franklin. Verified by Eric N. Smith. Amphibian and Reptile Diversity Research Center, University of Texas at Arlington (UTA A-58124). First county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 447 pp.).

This record completes its expected distribution throughout south Texas as it has previously been documented from all surrounding counties. The location is part of the south Texas brush country, with parts of the sand sheet extending into the northern part of the county, making the vegetation highly diverse and consisting of low to mid-sized woody and mostly thorny shrubs, vines, trees, and grasses, and a mixed composition of succulent and thorn brush vegetation in areas with sandy soils.

***LITHOBATES PALUSTRIS* (Pickerel Frog)**. USA: TENNESSEE: Hamilton Co.: Residential property off of Signal Forest Drive (35.191909°N, 85.341366°W; WGS 84). 4 August 2015. Joshua R. Ennen and Noah Ennen. Verified Floyd Scott. Center of Excellence for Field Biology, Austin Peay State University (APSU 19586, digital color photo voucher). New county record (Scott and Redmond 1996. Atlas of Amphibians in Tennessee. Austin Peay State University, Clarksville, Tennessee. Updated online version available at http://apbrwww5.apsu.edu/amatlas/index.html [accessed 7 August 2015]). One sub-adult found under a cedar tree at a residential area dominated by oak and hickory trees.

JOSHUA R. ENNEN, Tennessee Aquarium Conservation Institute, Chattanooga, Tennessee 37402, USA; e-mail: jre@tnaqua.org.

***LITHOBATES SYLVATICUS* (Wood Frog)**. USA: ARKANSAS: Carroll Co.: Ninestone land trust, 1.5 km NW Metalton (36.8445°N, 94.0858333°W; WGS 84). 13 June 2015. J. C. Neal. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 33361, photo voucher). Juvenile observed hopping across a trail at the edge of a glade. First county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.). Fills a distributional hiatus among adjacent Boone, Newton, Madison, and Benton counties.

MATTHEW B. CONNIOR, Life Sciences, Northwest Arkansas Community College, One College Drive, Bentonville, Arkansas 72712 USA (e-mail: mconnior@nwacc.edu); **JOSEPH C. NEAL**, 145 E. Cleburn Street, Fayetteville, Arkansas 72701, USA.

***OSTEOPILUS SEPTENTRIONALIS* (Cuban Treefrog)**. USA: ALABAMA: Lee Co.: 0.10 road km NW of Ingleside Dr. on Kinsley Ct. (32.58252°N, 85.45724°W; WGS 84). 12 November 2012. Charles H. Ray. Verified by Toby J. Hibbitts. Auburn University Natural History Museum (AUM 40229). New county record (Mount 1975. Reptiles and Amphibians of Alabama. Auburn University Agricultural Experiment Station, Auburn, Alabama. 347 pp.). To our knowledge, this is just the second documented record for *Osteopilus septentrionalis* in the state of Alabama, the first being an individual found in Mobile County in 2007 (Florida Museum of Natural History [UF 151411]). Our record is an adult female frog found on the inner vertical face of a fiberglass stepladder at a residence in Auburn, Alabama. The residence had received plantings from a nursery in the previous months. While undoubtedly an isolated occurrence, it adds to growing evidence of this species' ability to survive interstate transport. Specimen collected under General Scientific Collecting Permit No. 8309, issued by the Alabama Department of Conservation and Natural Resources, Wildlife and Freshwater Fisheries Division.

DAVID LAURENCIO (e-mail: norops@auburn.edu), **SCOTT GOETZ**, **CRAIG GUYER**, and **CHARLES H. RAY**, Auburn University Museum of Natural History, Department of Biological Sciences, 101 Rouse Life Sciences Building, Auburn University, Alabama 36849, USA.

TESTUDINES — TURTLES

***APALONE SPINIFERA* (Spiny Softshell)**. USA: FLORIDA: Escambia Co.: Perdido River (30.655631°N, 87.397761°W; WGS84). 27 March 2002. Dale R. Jackson and Robert N. Walker. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 175780, 4 photographic vouchers; specimen alive in captivity, 2015). New drainage record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.; Moler 2006. *In* Meylan [ed.], Biology and Conservation of Florida Turtles. Chelon. Res. Monogr. 3. 376 pp.; Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final report, Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.). The undocumented listing of this species in the Perdido River by Jackson (2005. *In* Meshaka and Babbitt [eds.], Amphibians and Reptiles: Status and Conservation in Florida. Kreiger Publ. Co., Malabar, Florida. 317 pp.) was based on this record. This small blackwater river, which flows 80 straight-line km southward to Perdido Bay on the Gulf of Mexico, is situated between the Escambia River and Mobile Bay drainages (both known to support the species) and forms the southernmost portion of the Alabama-Florida state border for much of its length. One of two small adult males observed basking at river's edge in stretch from 2 miles S of Barrineau Park downstream to County Road 184; most of this stretch on the Florida side was subsequently protected as the Perdido River Water Management Area following the survey in which this population was discovered.

A second, older specimen, in the Auburn University Museum of Natural History, is available from the Alabama side of the river, ca. 19.5 straight-line km downstream of UF 175780's capture site. AUM 25123, an adult male, was collected by G. Baldwin on 17 August 1976, 1.0 mile S of US 90, Baldwin Co. (georeferenced as 30.50752°N, 87.44736°W). We thank David Laurencio for providing data for the Alabama specimen.

***CHRYSEMYS PICTA* (Painted Turtle)**. USA: INDIANA: Tippecanoe Co.: Celery Bog (40.454519°N, 86.936141°W; WGS 84) 28 April 2015. Zachary Truelock. Verified by Kenneth Krysko. Florida Museum of Natural History (UF-Herpetology 176031, photo voucher). New county record (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. vii + 404 pp.). A single adult was observed and photographed basking on a log. Numerous others were seen but not photographed.

ZACH TRUELOCK, Purdue University, 580 McCutcheon Hall, West Lafayette, Indiana 47907, USA; e-mail: ztrueloc@purdue.edu.

***GLYPTEMYS INSCULPTA* (Wood Turtle)**. USA: WISCONSIN: Vernon Co.: Township of Whitestown (43.7°N, 90.6°W; WGS 84). 12 July 2009. Ben Johnston. Verified by Joshua M. Kapfer. Illinois Natural History Survey (INHS 2015a, photo voucher). New county record that completes a gap in the species' documented range (Casper 1996. Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Milwaukee Publ. Mus., Milwaukee, Wisconsin. 87 pp.). An individual Wood Turtle was encountered and photographed by Ben Johnston in the Kickapoo Valley Reserve within a dry-mesic forest and approximately 12 m upland from the Kickapoo River corridor. Adjacent habitat includes non-forested emergent wetlands, floodplain forests, fallow upland fields, and agricultural fields. The only published mention of this species in Vernon Co. (Pope 1930. Trans. Wisconsin Acad. Sci. Arts Lett. 25:273–284) was based on a specimen collected by W. R. Spellum in 1928 along the Bad Axe River (Milwaukee Public Museum, MPM 2291, currently listed as "presumed missing"). Our current report supplements six additional unvouchered observations that have been reported intermittently to the Wisconsin Department of Natural Resources' Natural Heritage Inventory database from 1977 through 2011 for Vernon Co.

BEN JOHNSTON, Kickapoo Valley Reserve, S3661 State Road 131, La Farge, Wisconsin 54639, USA (e-mail: ben.johnston@wisconsin.gov); **ANDREW F. BADJE** and **RICHARD A. STAFFEN**, Wisconsin Department of Natural Resources-Bureau of Natural Heritage Conservation, 101 S. Webster St., PO Box 7921, Madison, Wisconsin 53707-7921, USA.

***GRAPTEMYS GEOGRAPHICA* (Northern Map Turtle)**. USA: TENNESSEE: Lawrence Co.: Little Buffalo River in Laurel Hill Wildlife Management Area (35.380142°N 87.513106°W; NAD 83). 13 July 2015. Brian T. Miller. Verified by A. F. Scott. Austin Peay State University (APSU 19609, color photograph). First record for county (Scott and Redmond 2008, latest update: 25 May 2015. Atlas of Reptiles in Tennessee. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/(accessed 10 September 2015). An adult found alive in stream.

BRIAN T. MILLER (e-mail: brian.miller@mtsu.edu) and **MARSHALL S. BAUGHMAN**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

***GRAPTEMYS OUACHITENSIS* (Ouachita Map Turtle)**. USA: OKLAHOMA: Alfalfa Co.: Salt Fork of the Arkansas River, Great Salt Plains State Park (36.746963°N, 98.1337888°W; WGS 84). 7 October 2013. Gregory A. Geller and Deborah A. Geller. Verified by Peter V. Lindeman. Florida Museum of Natural History (UF

176019, 176020; photo vouchers). New county and tributary record (Lindeman 2013. The Map Turtle and Sawback Atlas: Ecology, Evolution, Distribution, and Conservation. University of Oklahoma Press, Norman. 460 pp.). Several male and female turtles observed basking on rocks downstream of Great Salt Plains Lake spillways. As the salinity of the lake water is reported to be approximately one-quarter that of the ocean (Hedglen 2009. Great Salt Plains State Park and National Wildlife Refuge, Encyclopedia of Oklahoma History and Culture; www.okhistory.org [accessed September 03, 2015]), future dietary and physiological studies of this population may prove of interest.

I thank Peter V. Lindeman for alerting me to the significance of these observations and Kenneth L. Krysko for processing the vouchers.

GREGORY A. GELLER, E7503 County Highway C, North Freedom, Wisconsin 53951, USA; e-mail: ggeller54@gmail.com.

***GRAPTEMYS PSEUDOGEOGRAPHICA KOHNII* (Mississippi Map Turtle)**. USA: TEXAS: Brazoria Co.: Freeport, Brazos River (tidal) approximately 10 river km upstream from mouth. (28.964739°N, 95.374234°W; WGS 84). 11 February 2015. Stephen Curtis and Rachel Byrne. Verified by Carl J. Franklin. Amphibian and Reptile Diversity Research Center, University of Texas at Arlington (UTADC 8570–8574, photo vouchers). New county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 447 pp.). Hatchling-sized (SCL = 37 mm) individual captured by hand from piling near a boat ramp. This area of the Brazos River is tidally influenced, and salinities of >10 ppt have been recorded at the site. Capture was following a high water flow event (flow = 24,100 cfs; USGS gauge 08116650) which may have displaced the animal to capture location. Salinity at time of capture was 2 ppt. This specimen increases range approximately 134 km (straight line distance) SE from Mill Creek, a Brazos River tributary, in Austin Co., Texas (VertNet database search, http://www.vertnet.org) and 80 km SW from another recent report in Fort Bend Co., Texas (Alleman et al. 2015. Herpetol. Rev. 46:565). Specimen collected under TPWD Scientific Research Permit SPR-0504-383.

STERNOTHERUS ODORATUS **(Eastern Musk Turtle)**. USA: PENNSYLVANIA: Montour Co.: Montour Preserve (41.096794°N, 76.663693°W; WGS 84), ca. 170 m elev. 21 June 2015. Sean M. Hartzell. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 175782, photo voucher). New county record (Hulse et al. 2001. Amphibians and Reptiles of Pennsylvania and the Northeast. Cornell University Press, Ithaca, New York. 419 pp.; www.paherpsurvey.org, accessed 21 June 2015). This record extends the range of *S. odoratus* within eastern Pennsylvania by ca. 25 km NE from the nearest previous record for this species in Northumberland Co. (CM 113393). Individual encountered basking along the shoreline of a small pond.

SEAN M. HARTZELL (e-mail: smh14844@huskies.bloomu.edu) and **AMBER L. PITT**, Department of Biological and Allied Health Sciences, Bloomsburg University of Pennsylvania, Bloomsburg, Pennsylvania 17815, USA (e-mail: apitt@bloomu.edu).

STERNOTHERUS ODORATUS **(Eastern Musk Turtle)**. USA: TENNESSEE: Lawrence Co.: Highway 240 (35.398939°N 87.382581°W, NAD 83), ca. 05. km NE of Buffalo River crossing. 13 July 2015. Brian T. Miller. Verified by A. F. Scott. Austin Peay State University (APSU 19608, color photograph). First record for county, which decreases the size of the conspicuous hiatus in records reported for central Tennessee by Scott and Redmond (2008, latest update: 25 May 2015. Atlas of Reptiles in Tennessee. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee.

Available at http://apsu.edu/reptatlas/ [accessed 13 July 2015]). An adult found alive on road.

BRIAN T. MILLER (e-mail: brian.miller@mtsu.edu) and **NICHOLAS A. GONDER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

***TERRAPENE CAROLINA CAROLINA* (Woodland Box Turtle)**. USA: INDIANA: Howard Co.: Kokomo, 3601–3699 Briarwick Dr. (40.443491°N, 86.140760°W; WGS 84). 15 June 2014. Aiden E. Stewart. Verified by Alan Resetar. Illinois Natural History Survey photo voucher (INHS 2015ar). New county record (Minton 2001. Amphibians & Reptiles of Indiana, 2nd ed. Indiana Academy of Science, Indianapolis. 404 pp.). Fills gap in distribution in north-central Indiana. Known from three of six adjacent counties.

AIDEN E. STEWART, **JENNIFER SCHOOLCRAFT**, and **MICHAEL S. FINKLER**, School of Sciences, Indiana University Kokomo, PO Box 9003, Kokomo, Indiana 46904-9003, USA (e-mail: mfinkler@iuk.edu).

***TERRAPENE CAROLINA CAROLINA* (Woodland Box Turtle)**. USA: PENNSYLVANIA: Clarion Co.: Intersection of State Road 478 and Freeman Road (41.168766°N, 79.657650°W; WGS 84). 27 May 2015. Elisabeth T. Regester. Verified by Walter Meshaka. Clarion University Vertebrate Collections and Museum (CUP AP500). Adult male. New county record extending range southeast from Venango Co., northeast from Butler Co., and north from Armstrong Co. (Hulse et al. 2001. Amphibians and Reptiles of Pennsylvania and the Northeast. Cornell University Press, Ithaca, New York. xii + 419 pp.; Pennsylvania Amphibian and Reptile Survey: www.paherpsurvey.org, accessed 27 May 2015).

ELISABETH T. REGESTER and **LAUREL T. REGESTER,** 725 Whitehall Road, Emlenton, Pennsylvania 16373, USA; **KURT J. REGESTER**, Department of Biology, Clarion University, Clarion, Pennsylvania 16214, USA (e-mail: kregester@clarion.edu).

***TRACHEMYS SCRIPTA* (Pond Slider)** USA: GEORGIA: Lumpkin Co.: Lake Zwerner, US 19 & Lake Zwerner, 0.61 mi NE, Dahlonega (34.550928°N, 83.963037°W; WGS 84). 23 June 2014. Grover Brown. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 173914). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Adult female was seen basking on a log in Yahoola Creek. Both *T. s. scripta* and *T. s. elegans* were seen at this location, so it is not known if one species was in fact native to the area, or whether both were introduced.

GROVER J. BROWN III, Department of Biological Sciences, The University of Southern Mississippi, 118 College Drive, Hattiesburg, Mississippi 39406 USA; e-mail: GroverJBrown@gmail.com.

***TRACHEMYS SCRIPTA ELEGANS* (Red-Eared Slider)** USA: TENNESSEE: Carrol Co.: Hwy 70 (35.844766°N, 88.573212°W; WGS 84). 30 May 2015. Lee J. Barton. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19557, color photo). First record for Carrol Co. (Scott and Redmond 2008 [latest update: 25 May 2015]. Atlas of Reptiles in Tennessee. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/, accessed 27 July 2015). Adult was found dead on the highway and photographed.

LEE J. BARTON, Freed-Hardeman University, 151 E. Main Street, Henderson, Tennessee 38340, USA: e-mail: lbarton@fhu.edu.

SQUAMATA — LIZARDS

***ANOLIS CAROLINENSIS* (Green Anole)**. USA: CALIFORNIA: Los Angeles Co.: Los Angeles (34.07801°N, 118.33476°W; WGS 84). 1 October 2013. Two adult males and two adult females collected in an urban neighborhood along the 300 block of N. June St. Gregory B. Pauly. Verified by Neftali Camacho. Natural History Museum of Los Angeles County (LACM 184412–184415). New county record and second state record. An additional 19 specimens were collected 1 August 2014 (LACM 185160–185178) and included a recent hatchling, adult females, and adult males. Additional juveniles and adults were observed but not captured on both days. All individuals were observed in an area with maximum extent of 315 m along a north-south axis and 300 m along an east-west axis. This area covers ca. 65,600 m^2 centered roughly on the intersection of N. June Street and Oakwood Avenue in the Hancock Park neighborhood of Central Los Angeles. Interviews with area residents indicated the anoles had been there since at least 2001. This is the first report of an established *A. carolinensis* population in the county, although a single escaped pet anole was previously found in the county (LACM 131565). The first state record of anoles is of an established population in San Diego Co. where they are found in Balboa Park, in and around the San Diego Zoo (Jones and Lovich 2009. *In* Jones and Lovich [eds.], Lizards of the American Southwest, pp. 50–52. Rio Nuevo Publishers, Tucson, Arizona).

Specimens were collected under California Department of Fish and Wildlife Scientific Collecting Permit No. SC4307.

GREGORY B. PAULY, Natural History Museum of Los Angeles County, Los Angeles, California 90007, USA (e-mail: gpauly@nhm.org); **DAVID B. BORTHWICK**, 325 Binscarth Road, Los Osos, California 93402, USA.

***ASPIDOSCELIS MOTAGUAE* (Giant Whiptail)**. USA: FLORIDA: Monroe Co.: Summerland Key, 594 West Shore Drive, Summerland Key (24.6528°N, 81.441°W; WGS 84). 7 August 2015. Kenneth L. Krysko, Claudia A. MacKenzie-Krysko, and Harrison W. Butchart. Verified by Matthew T. Fedler. Florida Museum of Natural History (UF-Herpetology 175793). First record from the Florida Keys and a new county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final report, Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.). Extends range ca. 132 km SW of the nearest known record and population in Miami-Dade Co. (UF-Herpetology 141595). The population on Summerland Key was first detected in 2014. At least 15 individuals of all size classes were observed.

KEVIN M. ENGE (e-mail: kevin.enge@myfwc.com) and **JONATHAN D. MAYS**, Florida Fish and Wildlife Conservation Commission, 1105 S.W. Willison Road, Gainesville, Florida 32601, USA; **KENNETH L. KRYSKO**, **CLAUDIA A. MacKENZIE-KRYSKO**, and **HARRISON W. BUTCHART**, Florida Museum of Natural History, Division of Herpetology, 1659 Museum Road, Gainesville, Florida 32611, USA; **SCOTT COMPTON**, 596 West Shore Drive, Summerland Key, Florida 33042, USA.

***ASPIDOSCELIS NEOMEXICANA* (New Mexico Whiptail)**. USA: ARIZONA: Navajo Co.: Petrified Forest National Park (PEFO) west of Rainbow Forest Museum (34.815480°N, 109.867766°W; NAD 83). 22 August 2010. David N. Velk. University of Arizona Museum of Natural History (UAZ 57584-PSV, digital photo voucher). Two additional digital photo voucher specimens (UAZ 57581-PSV, 57582-PSV) were found in the park in 2011. One digital photo voucher specimen (UAZ 57583-PSV) in 2011 and one collected specimen (UAZ 57573) in 2013 were found ca. 1 km outside of the

south park entrance near US Highway 180. All verified by George Bradley. New county record (Persons and Wright 1999. Herpetol. Rev. 30:207–209; Brennan and Holycross 2006. A Field Guide to Amphibians and Reptiles in Arizona. Arizona Game and Fish Department, Phoenix, Arizona. 150 pp.).

This species was previously known from only one location in Arizona, ca. 26 km N in PEFO in neighboring Apache Co. Intensive pitfall trapping and visual encounter survey efforts have been conducted throughout PEFO for over 15 years (Drost et al. 2001. *In* Proceedings of the Fifth Biennial Conference of Research on the Colorado Plateau, pp. 83–102. U.S. Geological Survey Report Series USGSFRESC/COPL/2001/24; Persons and Nowak. 2006. Inventory of Amphibians and Reptiles in Southern Colorado Plateau National Parks, 186 pp. U.S. Geological Survey Open File Report 2006-1132), suggesting that the species has only recently become established in the southern portion of the park. All specimens were found in sandy shrubland floodplains within plains grassland habitat. Fieldwork was supported by the National Park Service. Permits were issued by the Arizona Game and Fish Department (SP602226 CLS) and Northern Arizona University (IACUC 09-004).

IAIN D. EMMONS (e-mail: Iain.Emmons@nau.edu), **TREVOR B. PERSONS**, Northern Arizona University, Colorado Plateau Research Station, Box 5614, Flagstaff, Arizona 86011, USA (e-mail: Trevor.Persons@nau.edu); **DAVID N. VELK**, Gila Cliff Dwellings National Monument, Western National Parks Association, HC 68 Box 100, Silver City, New Mexico 88061, USA (e-mail: david.velk@wnpa.org); **ANDREW BRIDGES**, Petrified Forest National Park, Division of Resource Management, PO Box 2217, 1 Park Road, Petrified Forest, Arizona 86028, USA (e-mail: andrew_bridges@nps.gov).

***ASPIDOSCELIS TESSELATA* (Common Checkered Whiptail).** USA: COLORADO: Bent Co.: Setchfield State Wildlife Area (37.7557°N, 103.255°W; NAD 83). 14 August 2010. Daniel J. Martin. Verified as *A. tesselata* pattern class D by Harry L. Taylor. University of Colorado Museum (UCM AC-187, photo voucher). First confirmed record for this species in Bent Co. (Hammerson 1999. Amphibians and Reptiles in Colorado. University Press of Colorado, Niwot. 484 pp.; The Global Biodiversity Information Facility: GBIF Backbone Taxonomy 2013-07-01, http://www.gbif.org/species/2472276, accessed 1 Nov. 2014). Nearest known records from adjacent counties include: Otero (15 km), Las Animas (21 km), Baca (69 km); no records are reported for Prowers or Kiowa counties. An adult *A. tesselata* was found actively foraging at 0927 h in the sun near a juniper (*Juniperus* sp.). General habitat was juniper and short-grass prairie on top of a small mesa (approximately 1350 m elev.). There was a previous unconfirmed report of *A. tesselata* from Bent Co., "7.5 mi. NE Higbee" (Smith et al. 1965. Summary of the Distribution of the Herpetofauna of Colorado. Univ. Colorado Studies, Series in Biology 15:1–52).

This observation was made opportunistically during a survey for horned lizards (*Phrynosoma* spp.) funded by a Horned Lizard Conservation Society research grant.

DANIEL J. MARTIN, Natural Resource Ecology Laboratory, 1499 Campus Delivery, Colorado State University, Fort Collins, Colorado 80523-1499, USA (e-mail: danny.martin@colostate.edu); **LAURA E. R. MARTIN**, Department of Clinical Sciences, 1678 Campus Delivery, Colorado State University, Fort Collins, Colorado, 80523-1678, USA; **DAVID WOJNOWSKI**, College of Education & Human Development, 30 Pryor Street, Georgia State University, Atlanta, Georgia 30303-3083, USA; **BEN A. FISHER**, 7972 West 109th Avenue, Westminster, Colorado 80021, USA.

***CRYPTOBLEPHARUS* CF. *SCHLEGELIANUS* (Timor North Coast Snake-eyed Skink).** TIMOR-LESTE: Lautém District: Jaco Island (8.43°S, 127.32°E; WGS 84). 14 August 2015. Tom Martin and Barnabas Harrison. Verified by Andrew Kathriner and Sven Mecke. National Museum of Natural History, Smithsonian Institution, Herpetological Image Collection (USNM-HI 2846a–d, photo voucher). Easternmost record for Timor-Leste, and first record from Jaco, a 10 km^2, low-lying uninhabited island, 750 m E of mainland Timor-Leste's easternmost point (O'Shea et al. 2012. Asian Herpetol. Res. 3:114–126).

Cryptoblepharus schlegelianus (Mertens 1928) described based on SFM 15604, received in 1854 from the collection in Gießen, Germany (Mertens 1928. Zool. Anz. 78:82–89), listed as collected on Timor. However, our research show that material in Gießen was most likely collected by Salomon Müller on Pulau Semau, a small island off SW coast of Timor, near the port at Kupang (see Kaiser et al. 2011. Zookeys 109:19–86). As the point of origin for specimen shipments from the region, material was often erroneously labeled as having been collected on Timor. The species *C. schlegelianus* has only been reliably reported from coastal habitats on Semau (Brongersma 1942. Zool. Meded. Leiden. 24:125–152). A similar species has been collected at Tasi Tolu and Cristo Rei, both Dili District, and Com, Lautém District (O'Shea et al. 2015. Asian Herpetol. Res. 6:73–131), all Timor-Leste. Although similar to *C. schlegelianus*, these specimens exhibit differences in their pattern, scalation, and ecology (see O'Shea et al. 2015. *op. cit.*; HK unpubl. data), and we refer to them conservatively as *C.* cf. *schlegelianus*. Specimens observed on Jaco belong to this eastern, Timor Island population. Whereas *C. schlegelianus* was observed and collected in sandy beach environments on Semau, *C.* cf. *schlegelianus* has heretofore not been observed on sand, but only along rocky shores and on man-made concrete jetties. They have been observed in the splash-zone on rocks or nearby flotsam (Horner 2007. The Beagle, Suppl. 3:21–198).

On Jaco, TM and BH observed four specimens of *C.* cf. *schlegelianus* foraging along rocky shore (an unnumbered habitat photograph associated with USNM-HL 2846 in USNM database), in keeping with behavior and habitat choice of populations recorded at other locations in Timor-Leste and in contrast to those on Semau. Species appears to occur in populous aggregations unlike two other species on Timor-Leste, *C. leschenault* and *Cryptoblepharus* sp. 'Bakhita,' which have only been sighted singly or in pairs (O'Shea et al. 2015, *op. cit.*).

THOMAS MARTIN, Centre for Environmental and Marine Sciences, University of Hull, Scarborough Campus, Filey Road, Scarborough YO11 3AZ, United Kingdom (e-mail: tom_martin_2010@yahoo.co.uk); **BARNABAS HARRISON**, 5 Shackleton Court, 2 Maritime Quay, Isle of Dogs, London E14 3QF, United Kingdom (e-mail: barnabas.harrison@gmail.com); **HINRICH KAISER**, Department of Biology, Victor Valley College, 18422 Bear Valley Road, Victorville, California 92395, USA, and Department of Vertebrate Zoology, National Museum of Natural History, Smithsonian Institution, Washington, D.C. 20013, USA (e-mail: hinrich.kaiser@vvc.edu); **MARK O'SHEA**, Faculty of Science and Engineering, University of Wolverhampton, Wulfruna Street, Wolverhampton WV1 1LY, United Kingdom; and West Midland Safari Park, Bewdley, Worcestershire DY12 1LF, United Kingdom (e-mail: oshea@markoshea.info).

***EUTROPIS MACULARIA* (Bronze Grass Skink).** BANGLADESH: KHULNA DIVISION: Meherpur District: Amjhupi (23.450661°N, 88.411260°E; WGS 84), 22 m elev. 12 June 2015. Faysal Ahmad. Verified by Shayer Mahmood Ibney Alam. Zoology Museum,

Department of Zoology, Jagannath University, Dhaka (JnU/Zoo/M/Rep/Pho/2015/0005, photo voucher; adult specimen unnumbered); Zoological Reference Collection, Lee Kong Chian Natural History Museum, National University of Singapore, ZRC (IMG) 2.256. First record for Meherpur District. Previously reported from Rangamati District, Bandarban District under Chittagong Division, Sylhet Division and Dhaka Division (Mahony et al. 2009. Hamadryad 34:80–94). Found in litter of bamboo garden, besides paddy field.

MD. SHALAUDDIN (e-mail: salahuddinzadid@gmail.com), **FAYSAL AHMAD** (e-mail: faysal.nature@gmail.com), and **SHAYER MAHMOOD IBNEY ALAM**, Department of Zoology, Jagannath University, Dhaka 1100, Bangladesh (e-mail: shayermia@hotmail.com).

***GAMBELIA WISLIZENII* (Long-nosed Leopard Lizard)**. USA: ARIZONA: Navajo Co.: Petrified Forest National Park (PEFO), Stagecoach parcel (35.046254°N, 109.889643°W; NAD 83). 5 and 7 September 2012. Iain D. Emmons, Erika M. Nowak, and Robert Bowker. Verified by George Bradley. University of Arizona Museum of Natural History (UAZ 57501-PSV, 57502-PSV, 57503-PSV; digital photo vouchers). First records for the species in PEFO (Brennan and Holycross 2006. A Field Guide to Amphibians and Reptiles in Arizona. Arizona Game and Fish Department, Phoenix, Arizona. 150 pp.).

Although there are records for the species on the southern edge of the Colorado Plateau including a sighting 8 km W of the park boundary, these specimens represent the first records for the species in PEFO. The park has been intensively surveyed for over 15 years (Drost et al. 2001. *In* Proceedings of the Fifth Biennial Conference of Research on the Colorado Plateau, pp. 83–102. U.S. Geological Survey Report Series USGSFRESC/COPL/2001/24; Persons and Nowak 2006. Inventory of Amphibians and Reptiles in Southern Colorado Plateau National Parks, 186 pp. U.S. Geological Survey Open File Report 2006-1132). Two individuals were juveniles and one was a subadult, in open and flat sandy shrubland habitat near a floodplain.

We thank PEFO staff for logistical support. Fieldwork was funded by the National Park Service. Permits were issued by the Arizona Game and Fish Department (SP710162 CLS) and Northern Arizona University (IACUC 09-004).

IAIN D. EMMONS (e-mail: Iain.Emmons@nau.edu), **ERIKA M. ***HEMIDACTYLUS FRENATUS* (Common House Gecko)**. MÉXICO: BAJA CALIFORNIA: Municipality of Ensenada: Villa Jesus Maria, Taqueria Kassandra restaurant (28.28782°N, 113.99930°W; WGS 84), 29 m elev. 14 March 2015. L. E. Kabes, C. R. Mahrdt, J. H. Valdez-Villavicencio, and M. A. Stepek. Verified by Bradford D. Hollingsworth. San Diego Natural History Museum (SDSNH_HerpPC_05303, photo voucher). First state and northernmost record for this introduced species, extending its known distribution 198 airline km northwest from Santa Rosalia, Municipality of Mulegé, Baja California Sur (Luja et al. 2011. Herpetol. Rev. 42:240). Adult male found active in the shade at 1050 h on the exterior wall of the restaurant building.

LAURA E. KABES (e-mail: lkabes@sdnhm.org), **MELISSA A. STEPEK**, and **CLARK R. MAHRDT**, Department of Herpetology, San Diego Natural History Museum, San Diego, California 92102, USA; **JORGE H. VALDEZ-VILLAVICENCIO**, Conservación de Fauna del Noroeste, Ensenada, Baja California, 22785 (e-mail: j_h_valdez@yahoo.com.mx).

***HEMIDACTYLUS GARNOTII* (Indo-Pacific House Gecko)**. USA: CALIFORNIA: Los Angeles Co.: Torrance (33.86230°N, 118.31284°W; WGS 84). 18 and 20 April 2013. Gregory B. Pauly and Glen Yoshida. Verified by Aaron Bauer. Natural History Museum of Los Angeles County (LACM 183818, 183819). Additional specimens were collected 11 May 2013 (LACM 183877) and 28 September 2013 (LACM 184388–184389). New county and state record. Searches of this urban neighborhood suggest that the geckos are largely confined to a single house lot with gecko activity observed on the house and the cinder block walls around the lot. Geckos have been observed at this location since 2011, including adults, juveniles, and hatched and unhatched eggs. More than 20 observations of *H. garnotii* from this location have been submitted to the Reptiles and Amphibians of Southern California (RASCals) citizen science project (http://www.inaturalist.org/projects/rascals) by one of us (GSY). Geckos have been observed active at this location during all months of the year, including at air temperatures as low as 12.8°C in January (iNaturalist 533905). Further, recent hatchlings have been observed throughout the year including 14 and 26 December 2013 (iNaturalist 481438 and 487834, respectively) and 6 March 2014 (iNaturalist 555869). These observations demonstrate that eggs can successfully incubate and hatch even during the winter months, at least during the unusually warm 2013–2014 Southern California winter.

Orange Co.: Lake Forest (33.64177°N, 117.70660°W; WGS 84). 13–15 June 2013. Gregory B. Pauly and Robert Worrell. Verified by Aaron Bauer. LACM 184194–184196. New county and second state record. On 15 June 2013, an additional specimen was collected ca. 65 m ENE of the first collection site on an adjacent street (LACM 184197; 33.64183°N, 117.70590°W; WGS 84), and another *H. garnotii* was observed but not captured ca. 104 m NE of the first collection site on a low brick wall adjacent to vegetation (33.64213°N, 117.70557°W; WGS 84). All *H. garnotii* in this urban neighborhood were adults found on houses or on walls in front and backyards, often with overhanging or adjacent vegetation. In total, *H. garnotii* in Lake Forest were observed in an area spanning eight house lots (ca. 125 m) on two adjacent streets. Adult and juvenile geckos have been observed at this locality by one of us (RW) since 2009. A second Orange Co. population was documented 19 July 2014 by Anthony C. Huntley. A juvenile and adult female were collected in a neighborhood in the City of Orange (LACM 185970–185971; 33.79788°N, 117.79728°W; WGS 84). Both of the 2013 new county records resulted from observations first submitted as photo vouchers to the Natural History Museum of Los Angeles County (LACM) Lost Lizards of Los Angeles citizen science project which has been expanded into the RASCals project mentioned above.

Specimens were collected under California Department of Fish and Wildlife Scientific Collecting Permit #SC4307.

GREGORY B. PAULY, Natural History Museum of Los Angeles County, Los Angeles, California 90007, USA (e-mail: gpauly@nhm.org); **GLEN S. YOSHIDA**, 18531 Dorman Avenue, Torrance, California 90504, USA; **ROBERT WORRELL**, 24312 Partridge Circle, Lake Forest, California 92630, USA.

***HEMIDACTYLUS PLATYURUS* (Flat-tailed House Gecko)**. BANGLADESH: RAJSHAHI DIVISION: Naogaon District: Patiamly (25.060595°N, 88.440832°E; WGS 84), 26 m elev. 2 May 2014. Faysal Ahmad. Verified by Reza Khan. Zoology Museum, Department of Zoology, Jagannath University, Dhaka (JnU/Zoo/M/

Rep/Pho/2015/0006, photo voucher; adult specimen unnumbered); Zoological Reference Collection, Lee Kong Chian Natural History Museum, National University of Singapore (ZRC [IMG] 2.255, photo voucher). First record for Naogaon District, NW Bangladesh. Previously reported from Rangamati District, Bandarban District, and Cox's Bazar District under Chittagong Division (Mahony et al. 2009. Hamadryad 34:80–94). Adult collected from garden.

FAYSAL AHMAD (e-mail: faysal.nature@gmail.com), **SHAYER MAHMOOD IBNEY ALAM** (e-mail: shayermia@hotmail.com), and **TANIA KHONDAKAR**, Department of Zoology, Jagannath University, Dhaka 1100, Bangladesh (e-mail: tania.tuli@yahoo.com).

***HEMIDACTYLUS TURCICUS* (Mediterranean Gecko)**. USA: TEXAS: Kerr Co.: Mo Ranch, Hwy 1340 (30.06116°N, 99.47339°W; WGS 84), 607 m elev. 16 April 2015. Biodiversity Collections (formerly Texas Natural History Collections), The University of Texas at Austin (TNHC 95463). Individual collected on wall of Wynne Lodge at 2201 h (21°C). Menard Co.: Menard, Hwy 83 (E. Ellis St.) and FM 2092 (San Saba Ave.) (30.91719°N, 99.78625°W; WGS 84), 575 m elev. 18 April 2015. TNHC 95465. Individual collected on wall of a store front at 2300 h (16°C). Real Co.: Leakey, on Hwy 83 (Market St.) near intersection with Live Oak Circle (29.73309°N, 99.76110°W; WGS 84), 493 m elev. 16 April 2015. TNHC 95462. Individual collected on wall of a restaurant at 2109 h (22°C). These records partially fill a gap in the known distribution (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 447 pp.). Collections were made by William Farr and Limei Farr under a Texas Parks and Wildlife Hunting License (#792960031568). All specimens were verified by Travis J. LaDuc.

WILLIAM L. FARR, Houston, Texas 77096, USA; e-mail: williamfarr@sbcglobalo.net.

***HEMIDACTYLUS TURCICUS* (Mediterranean House Gecko)**. USA: TEXAS: Kimble Co.: Junction of Interstate 10 and U.S. Hwy 83 (30.507283°N, 99.776233°W; WGS 84), 520 m elev. 22 July 2012. Matthias Helb and Travis J. LaDuc. Verified by Kelsey Hornung. Biodiversity Collections (formerly Texas Natural History Collections), University of Texas at Austin (TNHC 85381). Junction at Interstate 10 and U.S. Hwy 377 (30.506583°N, 99.775717°W), 519 m elev. 31 August 1988. John Rawlins. Verified by Jose Padial. Carnegie Museum of Natural History (CM 125790). These two specimens are new county records (Dixon 2013. Amphibians and Reptiles of Texas. Texas A&M University Press, College Station, Texas. viii + 447 pp.), and fill in the known distribution of this non-native species as it continues to expand its range in Texas.

We thank Greg Pauly for pointing out the significance of these two specimens. TNHC specimen collected under Texas Parks and Wildlife Department Scientific Collecting Permit SPR-1092-917.

***HOLBROOKIA MACULATA PERSPICUA* (Prairie Earless Lizard)**. USA: TEXAS: Brisco Co.: Specimen was found 0.26 km NW of the Upper Canyon Trailhead, Caprock Canyons State Park (34.44922°N, 101.08283°W; WGS 84) 760 m elev. 13 July 2015. Thomas J. Belford. Verified by William E. Duellman. University of Kansas Digital Archives (KUDA 021417). First county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 447 pp.). A single adult specimen was found sitting beside the trail mid day. Fills a distribution gap among Swisher, Floyd, Hall, Armstrong, and Donley counties.

***OPHISAURUS ATTENUATUS ATTENUATUS* (Western Slender Glass Lizard)**. USA: KANSAS: Lyon Co.: County Road C (38.504413°N, 96.317920°W; WGS 84). 27 October 2013. Andrew Coleman and Greg Sievert. Verified by Curtis J. Schmidt. Sternberg Museum of Natural History (FHSM 16759). New county record (Collins 2010. Amphibians, Reptiles, and Turtles in Kansas. Sternberg Museum of Natural History, Fort Hays State University, Hays, Kansas. 312 pp.). Fills a gap in the known range of this species in eastern Kansas. A single adult male was found DOR following a night of heavy rain. This species is commonly observed in western Lyon Co. at the nearby Ross Natural History Reservation (a 60-ha plot of mixed prairie/woodland), but no specimens have been collected until now.

Collected under a State of Kansas Wildlife Collecting Permit (SC-078-2013).

***PLESTIODON GILBERTI* (Gilbert Skink)**. USA: CALIFORNIA: Yolo Co.: ca. 16 km by air SE Davis (38.468252°N, 121.583287°W; WGS 84), 7 m elev. 23 March 2014. Brian Hubbs and Brian Hinds. Verified by Neftali Camacho. Natural History Museum of Los Angeles County (LACM PC 1725, photo voucher). New county record (Rodgers and Fitch 1947. Univ. California Publ. Zool. 48[4]:169–220; Richmond and Jockusch 2007. Proc. Roy. Soc. Lond. B 274:1701–1708). Notably, this report places *Plestiodon*

gilberti west of the Sacramento River and north of the Sacramento-San Joaquin Delta, two significant hydrological impediments to dispersal in respect to known Sierra Nevada populations to the east and coastal populations to the south. Several lizards were observed under cover boards.

BRIAN HUBBS, P.O. Box 26407, Tempe, Arizona 85285, USA (e-mail: tricolorbrian@hotmail.com); **BRIAN HINDS,** 14530 Mulberry Dr., Whittier, California 90604, USA (e-mail: Brian@kingsnake.org).

***PODARCIS SICULUS* (Italian Wall Lizard)**. USA: NEW YORK: Westchester Co.: Hastings-on-Hudson (40.994542°N, 73.878746°W; WGS 84). 29 August 2015. Ben A. Goldfarb, Max R. Lambert, and Colin M. Donihue. Verified by Richard D. Durtsche. Yale Peabody Museum of Natural History (YPM HERR.019476). New state record (Gibbs et al. 2007. The Amphibians and Reptiles of New York State. Oxford University Press, New York. 504 pp.). This represents a northern expansion of the distribution for this exotic species in New York State; the species is known from New York City (Gossweiler 1975. Copeia 1975:584–585; Burke and Ner 2005. Northeast. Nat. 12:349–360). Multiple individuals were seen on the same date on multiple properties within a 3500-m^2 area incorporating three houses, a church, and a small strip mall. Specimen collection was authorized under Yale University IACUC protocol number 2015-10681.

SQUAMATA — SNAKES

***AGKISTRODON PISCIVORUS* (Cottonmouth)**. USA: GEORGIA: Glascock Co.: Found in small gum swamp along Sandhill Rd. (33.25511°N, 82.724383°W; WGS 84). 25 May 2015. S. Graham. Verified by John B. Jensen. Sul Ross State University (SRSU-D 5, digital photo voucher). New county record (Jensen et al. 2008. The Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Funding for this collection trip was provided by a grant from the Georgia Department of Natural Resources.

SEAN P. GRAHAM, Department of Biology, Geology, and Physical Sciences, Sul Ross State University, Alpine, Texas 79830, USA; e-mail: sean.graham@sulross.edu.

***AHAETULLA PULVERULENTA* (Brown Vine Snake)**. BANGLADESH: RAJSHAHI DIVISION: Naogaon District: Nazipur (25.040324°N, 88.442922°E; WGS 84), 23 m elev. 16 August 2013. Faysal Ahmad. Verified by Stephen Mahony. Zoology Museum, Department of Zoology, Jagannath University, Dhaka (JnU/Zoo/M/Rep/Pho/2015/0007, photo voucher; adult specimen unnumbered); Zoological Reference Collection, Lee Kong Chian Natural History Museum, National University of Singapore (ZRC [IMG] 2.257, photo voucher). First record for Naogaon District, NW Bangladesh. Previously reported from Sundarbans of Bangladesh as a first country record (Denzau and Denzau 2010. Herpetol. Notes 3:271–272). Adult collected in lower canopy of *Acacia* forest.

FAYSAL AHMAD (e-mail: faysal.nature@gmail.com), **SHAYER MAHMOOD IBNEY ALAM** (e-mail: shayermia@hotmail.com), and **TANIA KHONDAKAR**, Department of Zoology, Jagannath University, Dhaka 1100, Bangladesh (e-mail: tania.tuli@yahoo.com).

AMASTRIDIUM SAPPERI. MEXICO: QUERÉTARO: Municipio Arroyo Seco: Valle de Jalpan, Hwy 69 at Puente El Sabino (21.472715°N, 99.641983°W; WGS 84), 640 m elev. 27 July 2005. Robert W. Hansen and Dan Vermilya. Verified by Carl Franklin. Amphibian and Reptile Diversity Research Center, University of Texas at Arlington (UTADC 8561, photo voucher). First municipality record and second for Querétaro, extending the range 70 km WNW of La Cueva, Hidalgo (Lara-Tufiño et al. 2014. Revista Mexicana de Biodiversidad 85:654–657) and 55 km WNW of a specimen in Cornell University Museum of Vertebrates (CUMV 10386), from 2.8 miles (4.5 km) W of El Madroño, Querétaro (Calzada-Arciniega and Toscano Flores 2014. Bull. Maryland Herpetol. Soc. 50:42–43). We take this opportunity to clarify collection data associated with CUMV 10386 (collected 29 July 1973), given that there are two locality references with the specimen. According to the collector (W. J. Mautz, *in litt.*), the locality noted above is accurate and corresponds approximately to 21.275653°N, 99.154326°W, 1635 m elev., which exceeds the published elevational maximum of 1600 m (Lara-Tufiño et al. 2014, *op. cit.*). We follow Lara-Tufiño et al. (2014, *op. cit.*) and Lemos-Espinal and Smith (2015. Check List 11[art. 1642]:1–11) in regarding the northern populations as belonging to *A. sapperi*. The snake reported here was found on the road at 2120 h in thornscrub.

We thank William Mautz for examining his field notes from 1973.

ROBERT W. HANSEN, 16333 Deer Path Lane, Clovis, California 93619, USA (e-mail: hansenranch2@gmail.com); **DANIEL W. VERMILYA**, 38 Oak Hollow Road, Branford, Connecticut 06405, USA.

***BOA CONSTRICTOR* (Boa Constrictor)**. USA: PUERTO RICO: Municipality of Cabo Rojo: Cabo Rojo National Wildlife Refuge (17.978958°N, 67.170910°W; NAD 83). 10 November 2014. O. A. Diaz-Marrero. Verified by S. M. Boback. National Museum of Natural History, Smithsonian Institution (USNM Herp Image 2838a, b; photo vouchers). First municipality record for this exotic species; all previous reports were restricted to the Municipality of Mayaguez, located ca. 25 km north of Cabo Rojo National Wildlife Refuge. Reynolds et al. (2013. Biol. Invasions 15:953–959) concluded that Boa Constrictor introductions into Puerto Rico were likely related to the pet trade and that they genetically matched snakes belonging to the South American clade (*B. constrictor*), instead of *B. imperator,* the Mesoamerican species (Hynková et al. 2009. Zool. Sci. 26:623–631). It also represents the first report of this species from a protected area in Puerto Rico.

An interesting feature relates to why the snake was detected in the first place. It was a direct result of USDA/APHIS/Wildlife Services personnel tracking a radio-collared Mongoose (*Herpestes auropunctatus*) as part of a rabies study. The collar was broadcasting a mortality signal that was tracked to the fairly large gravid female *B. constrictor*, which was captured, sacrificed, and later underwent a necropsy that revealed a fully digested mongoose and its functional intact radio collar.

***CHRYSOPELEA ORNATA* (Ornate Flying Snake)**. BANGLADESH: RAJSHAHI DIVISION: Naogaon District: Nazipur (25.024012°N, 88.445153°E; WGS 84), 25 m elev. 12 August 2013. Faysal Ahmad. Verified by Stephen Mahony. Zoology Museum, Department of Zoology, Jagannath University, Dhaka (JnU/Zoo/M/Rep/Pho/2015/0008, photo voucher; adult specimen unnumbered); Zoological Reference Collection, Lee Kong Chian Natural History Museum, National University of Singapore (ZRC [IMG] 2.258, photo voucher). First record for Naogaon District, northwestern Bangladesh. Previously reported from Khulna, Chittagong and Syllhet Divisions (Hasan et al. 2014. Amphibians and Reptiles of Bangladesh—A Field Guide. Arannayk Foundation, Dhaka. 191 pp.). Adult collected in mid-canopy of *Mangifera* tree in human modified ecosystem; habitat includes primary forest, bush, and scattered forest close to human settlement.

FAYSAL AHMAD (e-mail: faysal.nature@gmail.com) and **SHAYER MAHMOOD IBNEY ALAM**, Department of Zoology, Jagannath University, Dhaka 1100, Bangladesh (e-mail: shayermia@hotmail.com).

***COLUBER CONSTRICTOR* (North American Racer)**. USA: ARKANSAS: Franklin Co.: off St. Hwy. 23 at White Oak (35.552646°N, 93.861238°W; WGS 84). 5 July 2015. C. T. McAllister and H. W. Robison. Verified by S. E. Trauth. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 33367). New county record completely filling a hiatus in northwest Arkansas among previous records for adjacent Crawford, Johnson, Logan, and Sebastian counties (Trauth et al. (2004. Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.). This female, found DOR, contained 14 oviductal eggs.

New county record partially filling a hiatus in far southwestern Arkansas among previous records for the adjacent counties of Howard and Polk (Trauth et al. (2004. Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.).

Specimen collected DOR under Scientific Collecting Permit (31120151) issued to CTM by Arkansas Game and Fish Commission.

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, Idabel, Oklahoma 74745, USA; e-mail: cmcallister@se.edu.

***LAMPROPELTIS CALLIGASTER* (Prairie Kingsnake)**. USA: TEXAS: Guadalupe Co.: Green Valley Road approximately 2.0 km W of the intersection of Green Valley Road and FM 1044 (29.64334°N, 98.15457°W; WGS 84). 13 June 2015. Romey L. Swanson and Erin Y. Swanson. Verified by Travis LaDuc. Texas Natural History Collection (TNHC 96347). New county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps, Texas A&M University Press, College Station. 447 pp.). This individual was collected DOR and measured 528.0 mm SVL and 43.7 g. This record fills a distributional gap in the Post Oak Savannah ecoregion adjacent to Bexar Co. to the west and Comal, Hays, and Caldwell counties to the north and northeast. Habitat adjacent to the road was comprised of active agriculture fields. We previously found another individual alive on 4 May 2015 approximately 2.2 km N within Comal

Co. at the intersection of Morningside Drive and Ron Road in New Braunfels, Texas (29.66345°N, 98.15495°W; WGS 84).

ERIN Y. SWANSON (e-mail: eyswanson@yahoo.com) and **ROMEY L. SWANSON**, New Braunfels, Texas 78130, USA (e-mail: romeyswanson@gmail.com); **CHRISTIAN L. SWANSON**, Bay City, Texas 78140, USA.

***LAMPROPELTIS GETULA SPLENDIDA* x *HOLBROOKI* (Desert/Speckled Kingsnake intergrade)**. USA: TEXAS: Hall Co.: 23.4 km S of Clarendon, on Hwy 70 (34.73060°N, 100.89854°W; WGS 84), 694 m elev. 11 July 2015. Brad Birchfield. Verified by William E. Duellman. University of Kansas Digital Archives (KUDA 12452). First county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 447 pp.). A single juvenile specimen was found crossing the road after dusk. Fills a distribution gap among Brisco, Motley, Cottle, and Childress counties.

***MICRURUS TENER* (Texas Coralsnake)**. USA: TEXAS: Starr Co.: 1357 FM 2686 (26.704281°N, 98.651436°W; WGS84). 15 August 2015. Mayra Oyervides and Frederic Zaidan III. Verified by Andrew Gluesenkamp. University of Texas-Pan American vertebrate museum (08151, photo voucher). First vouchered county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps, Texas A&M University Press, College Station, Texas. 447 pp.) Dixon (2013, *op. cit.*) notes the presence of the species in Starr Co. but extensive searches using online databases such as GBIF.org, VertNet.org, and literature failed to produce records of any vouchered specimens. One adult individual was found at 2355 h on FM 2686 moving across the road. The specimen was photographed *in situ*. The location is part of the south Texas brush country, characterized by frequent droughts and mostly low to mid-size thorny and woody shrubs, trees, and vines.

MAYRA OYERVIDES (e-mail: mgoyervides@broncs.utpa.edu) and **FREDERIC ZAIDAN III**, Department of Biology, University of Texas-Pan American, 1201 W. University Drive, Edinburg, Texas 78539, USA (e-mail: fzaidan@utpa.edu).

***NINIA ATRATA* (Hallowell's Coffee Snake)**. COLOMBIA: GUAVIARE: San José del Guaviare, vereda La María, embalse La María, Caño Arenales (2.529217°N, 72.692036°W; Bogotá WGS 84), 206 m elev. 5 October 2013. Martha L. Calderón and Guido F. Medina-Rangel. Verified by Martha L. Calderón. Colección de Reptiles, Instituto de Ciencias Naturales, Universidad Nacional de Colombia, Bogotá (ICN 12510–12512). This snake is known from eastern Panama to the Pacific lowlands of Ecuador, reaching northern Venezuela and Trinidad and Tobago, from sea level up to 1600 m elev. (McCranie and Wilson 1995. J. Herpetol. 29:224–232; Köhler 2008. Reptiles of Central America, 2nd ed. Herpeton, Offenbach. 400 pp.; Meza-Joya 2015. Check List 11:1584). In Colombia, is

known from the west (transandean) and the foothills of the Cordillera Oriental, in addition to a record in Leticia, Amazon department (Angarita-Sierra 2009. Pap. Avul. Zool. 49:277–288; Meza-Joya 2015, *op. cit.*). Although the snake is widely distributed to the west of the Eastern Cordillera and in the foothills east of it, until now there were no records in the Guyana Shield of Colombia. This is the first record for the Guyana region in Colombia, and extends species range ca. 140 km SW from the nearest known Colombian locality (Angarita-Sierra 2009, *op. cit.*). Permits were issued by Corporación para el Desarrollo Sostenible del Norte y Oriente Amazónico-CDA (Resolución No. DSGV-112, 25 October 2012).

GUIDO F. MEDINA-RANGEL, Instituto de Ciencias Naturales, Universidad Nacional de Colombia, Apartado Aéreo 7495, Bogotá D. C., Colombia; e-mail: gfmedinar@unal.edu.com

***NINIA DIADEMATA* (Ringneck Coffee Snake)**. MÉXICO: HIDALGO: Municipality of Tenango de Doria: El Damo (20.3332844°N, 98.2119598°W; WGS 84), 1537 m elev. 14 March 2015. Cristian Raúl Olvera-Olvera. Verified by Luis Canseco-Márquez. Colección Herpetológica Fotográfica, Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo, Pachuca (CH-CIB 31). First verified locality record within the municipality, extending the known range in the state ca.7.86 km S from the nearest record in the municipality of San Bartolo Tutotepec (Ramírez-Bautista et al. 2014. Los Anfibios y Reptiles del Estado de Hidalgo, México: Diversidad, Biogeografía y Conservación. Sociedad Herpetológica Mexicano, Pachuca, Hidalgo, México. xi + 387 pp.). Ramirez-Bautista et al. (2014, *op. cit.*) did not a specific locality within the municipality of Tenango de Doria, but did depict an individual from that municipality in Foto 214. The snake reported here, along with eight others of the same species, were found in a pasture under a rock on a cattle ranch.

LEONARDO FERNÁNDEZ-BADILLO, Laboratorio de Sistemática Molecular, Centro de Investigaciones Biológicas (CIB), Universidad Autónoma del Estado de Hidalgo, A.P. 1-69 Plaza Juárez, Pachuca, Hidalgo, México and Predio Intensivo de Manejo de Vida Silvestre X-Plora Reptilia, Reyna de la Esperanza # 107. ***OPHEODRYS AESTIVUS* (Rough Greensnake)**. USA: ARKANSAS: Lee Co.: Lone Point Campground at Bear Creek Lake off County Rd. 223, St. Francis National Forest (34.715334°N, 90.695649°W; WGS 84). 6 July 2008. T. Wilcoxen. Verified by S. E. Trauth. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 33369, photo voucher). New county record (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.). This record partially fills a hiatus in eastern Arkansas (Crowley's Ridge) among previous records for adjacent Phillips and St. Francis counties.

TRAVIS E. WILCOXEN, Department of Biology, Millikin University, Decatur, Illinois 62522, USA (e-mail: twilcoxen@mail.millikin.edu); **CHRIS T. McALLISTER**, Science and Mathematics Division, Eastern Oklahoma State College, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu).

***OPHEODRYS AESTIVUS* (Rough Greensnake)**. USA: TENNESSEE: Tipton Co.: Ballard Slough (35.55195°N, 89.88204°W; WGS 84). 5 May 2015. Robert Colvin, Jeremy Dennison, and Jake Yoes. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19583 photo voucher). First county record (Scott and Redmond 2008. Atlas of Reptiles in Tennessee. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. http://www.apsu.edu/reptatlas [updated 28 July 2014; accessed 22 July 2015]).

ROBERT COLVIN (e-mail: Rob.Colvin@tn.gov), **JEREMY DENNISON** (e-mail: Jeremy.Dennison@tn.gov), and **JAKE YOES**, Tennessee Wildlife Resources Agency, Region I, 200 Lowell Thomas Drive, Jackson, Tennessee 38301, USA (e-mail: jyduck1@hotmail.com).

***PANTHEROPHIS GUTTATUS* (Red Cornsnake)**. USA: TENNESSEE: Loudon Co.: 35.720863°N, 84.2491712°W (WGS 84), 263 m elev. 6 June 2015. Barbara Grove. Verified by John Jensen. Auburn University Natural History Museum (AHAP-D 1072, photo voucher). This observation represents a new county record, although the species is known from surrounding counties (Scott and Redmond 2008 <updated 25 May 2015>. Atlas of Reptiles in Tennessee. The Center of Excellence for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/; accessed 12 June 2015). This adult snake was found dead in garden netting.

BARBARA GROVE, Loudon, Tennessee 37774, USA; **DAVID A. STEEN**, Auburn University Department of Biological Sciences, Auburn, Alabama 36849, USA (e-mail: DavidASteen@gmail.com).

***PANTHEROPHIS OBSOLETUS* (Western Ratsnake)**. USA: IOWA: Winneshiek Co.: Cliffs along Upper Iowa River (43.4317°N, 91.9363°W; WGS 84). 21 June 2015. Mathew Terronez. Verified by Benjamin Lowe. Photographic record deposited in the James Ford Bell Museum (JFBM P503) as well as on HerpMapper.org (HM 59209; www.herpmapper.org/record/59209). Kayaker observed pair of adult ratsnakes along cliff directly below a cliff swallow community. LeClere (2013. A Field Guide to the Amphibians and Reptiles of Iowa. ECO Herpetological Publishing & Distribution, Rodeo, New Mexico. 350 pp.) lists a pre-1950 record for this species in Winneshiek Co. To the best of our knowledge this observation represents an updated county record for *P. obsoletus* in Winneshiek Co., Iowa. We thank Mathew Terronez for reporting his observation to HerpMapper.org.

CHRISTOPHER E. SMITH (e-mail: Christopher.Smith@HerpMapper.org) and **DON BECKER**, HerpMapper.org. 6510 Mosswood Ln NE, Cedar Rapids, Iowa 52402, USA (e-mail: Don.Becker@HerpMapper.org).

***PANTHEROPHIS SPILOIDES* (Gray Ratsnake)**. USA: INDIANA: Tippecanoe Co.: Ross Hills Park (40.40454°N, 87.072579°W; WGS 84) 2 September 2015. Zachary Truelock. Verified by Kenneth Krysko. Florida Museum of Natural History (UF-Herpetology 176030, photo voucher). New county record (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. vii + 404 pp.). An adult was observed crawling along the forest floor.

ZACH TRUELOCK, Purdue University, 580 McCutcheon Hall, West Lafayette, Indiana 47907, USA; e-mail: ztrueloc@purdue.edu.

***PORTHIDIUM LANSBERGII* (Lansberg's Hognosed Pitviper)**. COLOMBIA: HUILA: Gigante, vereda Matambo, Finca La Ensillada (2.37515833°N, 75.637275°W; Bogotá WGS 84), 985 m elev. 8 November 2014. Y. R. López Perilla. Verified by G. Cárdenas-Arévalo. Colección de Reptiles, Instituto de Ciencias Naturales, Universidad Nacional de Colombia, Bogotá (ICN 12533). Finca La Enea (2.3478278°N, 75.631322°W; Bogotá WGS 84), 889 m

elev. 10 October 2014. Guido F. Medina-Rangel. Verified by G. Cárdenas-Arévalo. ICN 12534. This species is known from central and eastern Panama, northern Colombia, and Venezuela, from sea level to 1000 m elev. (www.reptile-database.org; 8 Sept 2015); it was not recorded in the Biogeographic Chocó region, and records from Ecuador are *Porthidium arcosae* (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere, Vol. I. Comstock/Cornell University Press, Ithaca, New York. 503 pp.). This snake is found in arid and semiarid plains in Colombia, from northern Choco and Antioquia, coastal Caribean lowlands, and from Rio Magdalena valley, up to Honda, Tolima (Nicéforo-María 1930. Revista de la Sociedad Colombiana de Ciencias Naturales 19:96–104; Campbell and Lamar 2004, *op. cit.*). This record extends the range ca. 325 km S from the nearest known locality around Honda, Tolima department, Colombia (Niceforo-Maria 1930, *op. cit.*; Campbell and Lamar 2004, *op. cit.*). Specimen collected under research permits from Autoridad Nacional de Licencias Ambientales –ANLA (Resolución No. 0899, 15 May 2009).

***SISTRURUS TERGEMINUS EDWARDSII* (Desert Massasauga)**. USA: ARIZONA: Graham Co.: San Carlos Apache Reservation,

Ash Flat, Indian Route 8, 2.3 km E jct with Indian Route 19 (33.291772°N, 109.904512°W; WGS 84). AOR. 2 June 2015. James Beauchamp and Ben Calvert. Verified by Andrew T. Holycross. University of Arizona Museum of Natural History (UAZ 57630-PSV). We first observed *Sistrurus tergeminus edwardsii* on Ash Flat in early July 2001, and since that time we have observed 8–9 additional individuals crossing Indian Route 8 between its intersections with Indian Routes 19 and 11 (between 33.301226°N, 109.926970°W and 33.271778°N, 109.852959°W) on Ash Flat. Most of these have been DOR, only two were encountered during daylight, and all were observed during the period May–September.

These observations extend the known distribution of the species 78 km NW of an historical record (CA 12996) obtained by D. B. Carver in 1944 from "21 miles east of Safford" at 1006 m elevation at the northern limit of the San Simon Valley (A. T. Holycross, pers. comm.). Our record is also a new elevational maximum for *S. t. edwardsii* (1548 m is the maximum elevation for the section of road noted above) (A. T. Holycross, pers. comm.). Perhaps most significantly, of the several historical populations of *S. t. edwardsii* recorded in Arizona, only one was demonstrably extant prior to our discovery. The number, duration, and recency of our observations demonstrate that Arizona has a second, and previously undocumented, viable population of *S. t. edwardsii*. The Ash Flat population is ca. 200 km NNW of what was previously presumed to be the last population of the species in Arizona.

JAMES BEAUCHAMP, 1134 E Ruth Avenue, Phoenix, Arizona 85020, USA (e-mail: jimmyddc@yahoo.com); **BEN CALVERT**, 3710 N 35th Street, Phoenix, Arizona 85018, USA.

***STORERIA DEKAYI WRIGHTORUM* (Midland Brownsnake)**. USA: TENNESSEE: Hardin Co.: Horse Creek Wildlife Sanctuary (35.123942°N, 88.172383°W; WGS 84). 22 July 2015. Lee J. Barton, Joshua M. Hall, and Joshua P. Kee. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19597, color photo). First record for Hardin Co. (Scott and Redmond 2008 [latest update: 25 May 2015]. Atlas of Reptiles in Tennessee. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/, accessed 9 September 2015). Juvenile was captured in grass near the water's edge of Horse Creek.

LEE J. BARTON, Freed-Hardeman University, 151 E. Main Street, Henderson, Tennessee 38340, USA (e-mail: lbarton@fhu.edu); **JOSHUA P. KEE**, Austin Peay University, 601 College St., Clarksville, Tennessee 37044, USA; **JOSHUA M. HALL**, Auburn University, Auburn, Alabama 36849, USA.

***SONORA SEMIANNULATA* (Western Groundsnake)**. USA: OKLAHOMA: Pushmataha Co.: Pushmataha Wildlife Management Area (34.50549°N, 95.40022°W; WGS 84), 321 m elev. 26 May 2015. Nicholas A. Huron, Aaron D. Geheber, Elyse D. Ellsworth. Verified by Jessa L. Watters. Sam Noble Oklahoma Museum of Natural History (OMNH 44198). New county record (Sievert and Sievert 2011. A Field Guide to Oklahoma's Amphibians and Reptiles. Oklahoma Department of Wildlife Conservation, Oklahoma City, Oklahoma. 211 pp.). The nearest known vouchered specimens are from ca. 53.3 km to the S in Choctaw Co., Oklahoma (OMNH 26935, 26960, 27057, 27058). This specimen fills a gap in the known distribution of this species in Oklahoma. One adult male (212.0 mm SVL; 47.0 mm tail length; 7.7 g) collected at the Pushmataha Wildlife Management Area underneath a slab-like rock, atypical to the surrounding area, roughly 3 m from a small, well-vegetated pond containing a circle of pine trees and smaller deciduous trees. Specimen collected under an Oklahoma Department of Wildlife Conservation Scientific Collecting Permit (#6105) issued to NAH.

BRENDAN B. HEITZ (e-mail: flipthrow94@gmail.com), **ELYSE D. ELLSWORTH** (e-mail: Elyse.D.Ellsworth-1@ou.edu), **NICHOLAS A. HURON** (e-mail: nahuron@ou.edu), **AARON D. GEHEBER** (e-mail: Aaron.D.Geheber-1@ou.edu), and **CAMERON D. SILER,** Herpetology Collections, Sam Noble Oklahoma Museum of Natural History, University of Oklahoma, 2401 Chautauqua Avenue, Norman, Oklahoma, 73072-7029, USA (e-mail: camsiler@ou.edu).

***STORERIA OCCIPITOMACULATA* (Red-bellied Snake)**. USA: GEORGIA: Johnson Co.: Bartow-Dublin Rd. (32.76693°N, 82.69469°W; WGS 84). 27 May 2015. S. Graham. Verified by John B. Jensen. Sul Ross State University (SRSU-D 8-9, digital photo vouchers). New county record (Jensen et al. 2008. The Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Found under leaf litter on edge of swamp. Funding for this collection trip was provided by a grant from the Georgia Department of Natural Resources.

SEAN P. GRAHAM, Department of Biology, Geology, and Physical Sciences, Sul Ross State University, Alpine Texas 79830, USA; e-mail: sean.graham@sulross.edu.

***TANTILLA NIGRICEPS* (Plains Black-headed Snake)**. USA: TEXAS: Gaines Co.: 4.8 km W of Co. line, just S of Hwy 180 (32.694232°N, 102.257752°W; WGS 84). 12 May 2012. N. Taylor. Verified by Toby Hibbitts. Sul Ross State University (SRSU-D 21–24, digital photo vouchers). New county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 447 pp.).

NATHAN CALEB TAYLOR (e-mail: ntay8638@sulross.edu) and **SEAN P. GRAHAM**, Department of Biology, Geology, and Physical Sciences, Sul Ross State University, Alpine, Texas 79830, USA (e-mail: sean.graham@sulross.edu).

***THAMNOPHIS EQUES MEGALOPS* (Brown Gartersnake)**. USA: ARIZONA: Mohave Co.: Beal Lake Conservation Area, Havasu National Wildlife Refuge (34.776895°N, 114.53217°W; WGS 84). 29 April 2015. Michael B. Lester. Verified by George Bradley. University of Arizona (UAZ 57631-PSV, photo voucher). Considered extirpated from the Colorado River, this is the first sighting of *T. eques* along the main stem of the Colorado River in over a century (USFWS 2014. Endangered and Threatened Wildlife and Plants; Threatened Status for the Northern Mexican Gartersnake and Narrow-Headed Gartersnake; Final Rule. Federal Register 79:38677–38746). Nearest known specimen is from Clark Co., Nevada near Fort Mohave, Mohave County, Arizona recorded in 1911 (de Queiroz and Smith 1996. Herpetol. Rev. 27[3]:155). In 2012, a population was discovered along the Bill Williams River, near Swansea, Arizona (Cotten et al. 2013. Herpetol. Rev. 44[1]:111), approximately 90 km SE of the current sighting.

Snake was found moving slowly between habitat restoration areas (*Prosopis pubescens, Salix exigua, Pluchea sericea, Tamarix* sp.), approximately 75–100 m from water. Most of tail missing due to injury. Also seemed to have recently eaten, as it was found with a swollen abdomen.

MICHAEL B. LESTER (e-mail: mlester126@gmail.com) and **JARROD B. SWACKHAMER**, Great Basin Bird Observatory, 1755 E Plumb Ln #256a, Reno, Nevada 89502, USA.

***THAMNOPHIS SAURITUS* (Eastern Ribbonsnake)**. USA: MICHIGAN: Wexford Co.: 3.5 km N of Mesick (44.435373°N, 85.694218°W; WGS 84), 252 m elev. 24 June 2015. John G. Phillips. Verified by Kirsten E. Nicholson. Central Michigan University Museum of Cultural and Natural History (MCNH 2015.010, photo voucher). New county record (Holman 2012. The Amphibians and Reptiles of Michigan: A Quaternary and Recent Faunal Adventure. Wayne State University Press, Detroit, Michigan. 528 pp.; Michigan Herpetological Atlas 2015. Available at: http://miherpatlas.org, accessed 12 November 2015). This specimen fills a gap in the distribution, as *T. sauritus* has been recorded from all surrounding counties. Snake was found swimming across the Manistee River (approx. 30 m wide at that sections).

Special thanks to Angela Reidel at MCNH for accessioning this record. Field support was provided by M. Phillips, G. McPheeters, and M. Phillips.

JOHN G. PHILLIPS, Department of Biological Sciences, University of Tulsa, Tulsa, Oklahoma 74104, USA; e-mail: john-phillips@utulsa.edu.

***THAMNOPHIS SIRTALIS* (Eastern Gartersnake)**. USA: ALABAMA: Coosa Co.: Coosa Wildlife Management Area, Cahaba & Columbiana Forever Wild Tracts, 5.0 km NNW of AL Hwy 22 and Coosa CR 29 intersection (Kellys Crossroads) (32.87081°N, 86.36947°W; WGS 84). 19 May 2015. E. Soehren, J. Trent, and T. Rush. Verified by David Laurencio. Auburn University Natural History Museum (AUM AHAP-D 1106, digital photo voucher). New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University, Alabama. 347 pp.). Adult encountered actively moving over ground within mature, montane *Pinus palustris* (Longleaf Pine) forest. This record fills in gap among Chilton, Elmore, and Tallapoosa counties (Mount 1975, *op. cit.*) and was vetted through examination of online museum holdings (VertNet) and literature review (Zoological Record).

Distribution Records for Louisiana Amphibians and Reptiles

Over the past few decades there has been an increase in efforts to document the geographical distribution of the Louisiana herpetofauna (Dundee and Rossman 1989; Boundy 2004; Rosenzweig et al. 2007; Boundy and Gregory 2012). Even with the increased effort, there is still a lack of documented records for many widespread species (Conant and Collins 1998), particularly in the northeastern portion of the state (Reid et al. 2014). Here we report a total of 48 records that help to fill distributional gaps primarily in the northeastern region of Louisiana, but other parts of the state as well. Most of these parish records are a result of surveys and class collections conducted by the University of Louisiana at Monroe (ULM) Herpetology Lab. Geographic coordinates are based on the WGS 84 datum. Voucher specimens are deposited in the University of Louisiana at Monroe Museum of Natural History Herpetology collection (NLU). Photo vouchers were deposited in the Florida Museum of Natural History Herpetology collection, with the digital image UF-Herpetology designation shortened to UF in the species accounts below. Specimen identification was verified by Neil Douglas. Standard English names follow Crother (2012).

CAUDATA — SALAMANDERS

***AMBYSTOMA TALPOIDEUM* (Mole Salamander).** Caldwell Par.: Boeuf Wildlife Management Area (32.12453°N, 91.90636°W). 19 June 2006. Matthew D. Brown. NLU 70709, 70710. New parish record.

***AMPHIUMA TRIDACTYLUM* (Three-toed Amphiuma).** Caldwell Par.: Boeuf Wildlife Management Area, compartment 13 (32.03731°N, 91.97767°W). 26 June 2005. Matthew D. Brown and John E. Quinn 4th. NLU 70711. New parish record. Helps fill gap in north-central Louisiana. Located near an alligator hole. East Carroll Par.: Bayou Macon Wildlife Management Area (32.80190°N, 91.31560°W). 8 August 2006. Ashley N. Hudson. NLU 70712. New parish record. Helps fill gap in northeastern corner of Louisiana.

***SIREN INTERMEDIA NETTINGI* (Western Lesser Siren).** Catahoula Par.: Boeuf Wildlife Management Area, Enterprise Tract (31.92245°N, 91.89134°W). 7 November 2006. Matthew D. Brown. NLU 70713, 70714, 70715; Boeuf Wildlife Management Area (31.95167°N, 91.87255°W). 13 October 2013. Clayton R. Faidley. NLU 70716. New parish record. Fills gap in northeastern Louisiana. Tensas Par.: Buckhorn Wildlife Management Area, Brushy Lake (32.04426°N, 91.36586°W). 24 March 2012. ULM Advanced Herpetology Class. NLU 70717. New parish record. Fills gap in northeastern Louisiana. Caught in an aquatic drift fence in Brushy Lake.

ANURA — FROGS

***ELEUTHERODACTYLUS CYSTIGNATHOIDES* (Rio Grande Chirping Frog).** Rapides Par.: Alexander State Forest Wildlife Management Area, near Indian Creek Reservoir (31.09197°N, 92.46948°W). 22 May 2013. Clayton F. Faidley. NLU 70718. This is a new parish record for this introduced species, found in a rural location rather than the larger cities where it has previously been recorded in Louisiana. Found in a wooded area by a boat launch on Indian Lake, where several males were calling. The locality is within 1.5 km of a large plant nursery.

***HYLA AVIVOCA* (Bird-voiced Treefrog).** Lincoln Par.: Middle Fork of Bayou D'Arbonne (32.71983°N, 92.53183°W). 28 May 2009. Thomas M. Pardue. NLU 70719. New parish record. Near Gill's Ferry boat launch. Union Par.: Middle Fork of Bayou D'Arbonne (32.72153°N, 92.53201°W). 28 May 2009. Thomas M. Pardue. NLU 70720. New parish record. Near Gill's Ferry boat launch.

***HYLA SQUIRELLA* (Squirrel Treefrog).** East Carroll Par.: Bayou Macon Wildlife Management Area (32.82846°N, 91.31704°W). 11 November 2006. Ashley N. Hudson. NLU 70721. New parish record. Madison Par.: Tensas River National Wildlife Refuge (32.31752°N, 91.37711°W). 6 August 2009. Thomas M. Pardue. UF 173946. New parish record. Photographed under the overhang of the refuge headquarters building. Morehouse Par.: Upper Ouachita National Wildlife Refuge, near Mollicy Bayou (32.88710°N, 92.03495°W). 5 June 2012. Charles D. Battaglia. NLU 70722. New parish record. Found in a PVC pipe near a drift fence array by Mollicy Bayou. Tensas Par.: St. Joseph, off Hwy 128 (31.92446°N, 91.24049°W). 24 March 2012. Charles D. Battaglia and Matthew L. Reid. NLU 70723. New parish record. Fills in the northeastern range in Louisiana. On the outside wall of a convenience store.

***LITHOBATES PALUSTRIS* (Pickerel Frog)**. Madison Par.: Tensas River National Wildlife Refuge (32.34979°N, 91.31719°W). 6 August 2009. Thomas M. Pardue. UF 173947. New parish record. Photographed under air conditioning unit adjacent to a refuge maintenance building.

***PSEUDACRIS CRUCIFER* (Spring Peeper)**. East Carroll Par.: Bayou Macon Wildlife Management Area (32.84076°N, 91.32961°W). 20 February 2005. Ashley N. Hudson and Amy N. Wall. NLU 70724. New parish record. Helps fill gap in northeastern Louisiana.

CROCODYLIA — CROCODILIANS

***ALLIGATOR MISSISSIPPIENSIS* (American Alligator)**. Caldwell Par.: Boeuf Wildlife Management Area, (32.02254°N, 91.95168°W). 4 November 2013. Clayton R. Faidley. UF 173948. New parish record. Near bunkhouse in ditch. East Carroll Par.: Bayou Macon Wildlife Management Area (32.83379°N, 91.28793°W). 17 May 2005. Ashley N. Hudson. UF 173949. New parish record. Madison Par.: Tensas River National Wildlife Refuge, Whitney Lake (32.31287°N, 91.36588°W). 21 June 2014. Charles D. Battaglia and John L. Carr. Off of Quebec Rd. along the wildlife drive. UF 173950. New parish record.

TESTUDINES — TURTLES

***APALONE MUTICA* (Smooth Softshell)**. Allen Par.: Ouiska Chitto Creek (30.67899°N, 92.89987°W). 25 May 2011. Field Biology Class. NLU 70725. A new parish record and the first in the Calcasieu River basin. Morehouse Par.: Sandbar on E bank of Ouachita River (32.99560°N, 92.07258°W). 10 July 2001. John L. Carr. NLU 70726, 70727. New parish record. Hatchling vouchers from a nest found in the sandbar.

***CHELYDRA SERPENTINA* (Snapping Turtle)**. East Carroll Par.: Bayou Macon Wildlife Management Area (32.84970°N, 91.28854°N). 11 March 2006. Ashley N. Hudson, Adrian S. Chesh, and J. A. Incalcaterra. NLU 70728. New parish record.

***CHRYSEMYS DORSALIS* (Southern Painted Turtle)**. LaSalle Par.: Dewey W. Wills Wildlife Management Area, DOR on Hwy 28 south of Catahoula Lake (31.46401°N, 92.10667°W). 2 June 2007. John. L. Carr. NLU 70729. New parish record.

***KINOSTERNON SUBRUBRUM HIPPOCREPIS* (Mississippi Mud Turtle)**. Tensas Par.: Buckhorn Wildlife Management Area, margin of Brushy Lake (32.04498°N, 91.36530°W). 5 April 2008. John L. Carr. NLU 70730. Big Lake Wildlife Management Area (32.19829°N, 91.47823°W). 30 March 2008. Kody J. Chase. NLU 70731. New parish record. LaSalle Par.: Dewey W. Wills Wildlife Management Area, AOR on Hwy 28 (31.46643°N, 92.10435°W). 7 June 2014. Charles D. Battaglia, Matthew L. Reid, and Matthew S. Herron. UF 173951. New parish record.

***MACROCHELYS TEMMINCKII* (Alligator Snapping Turtle)**. Allen Par.: Barnes Creek at bridge on Martin Tram Rd. (30.45428°N, 93.04286°W). 17 July 2012. Thomas M. Pardue. UF 173952. New parish record. Photographed basking on fallen tree (see Carr et al. 2011, for other instances of basking in Louisiana). Caldwell Par.: Boeuf Wildlife Management Area, AOR on Big Ridge Rd. (32.04472°N, 91.95348°W). 16 May 2013. Clayton R. Faidley, John L. Carr, and Lisa D. Brown. UF 173953. New parish record. Iberia Par.: Avery Island (29.90624°N, 91.91206°W). 22 April 2014. Cody L. Townsend. UF 173954. New parish record. Found during a ULM class fieldtrip. Madison Par.: Nest found 4.7 km E, 3.6 km S of Waverly (32.41310°N, 91.36097°W). 22 May 2009. Amity A. Bass. NLU 70637. New parish record. Hatchling preserved as a voucher.

***PSEUDEMYS CONCINNA* (River Cooter)**. Caldwell Par.: Boeuf Wildlife Management Area, in woods by Horseshoe Lake (31.94692°N, 91.91745°W). 18 February 2012. Clayton R. Faidley. NLU 70732. New parish record. Shell remains.

***STERNOTHERUS CARINATUS* (Razor-backed Musk Turtle)**. Caldwell Par: Boeuf River (32.17474°N, 91.94520°W). 09 July 2006. Ashley N. Hudson and John L. Carr. NLU 70733. New parish record. Shell remains. East Carroll Par.: Bayou Macon Wildlife Management Area (32.80206°N, 91.31550°W). 8 August 2006. Ashley N. Hudson. NLU 70734. New parish record.

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle)**. East Carroll Par.: Bayou Macon Wildlife Management Area (32.79783°N, 91.31867°W). 3 April 2006. Ashley N. Hudson, Amy N. Wall, and Adrian S. Chesh. NLU 70735. New parish record.

***TERRAPENE CAROLINA TRIUNGUIS* (Three-toed Box Turtle)**. East Carroll Par.: Bayou Macon Wildlife Management Area (32.84940°N, 91.31306°W). 25 August 2005. Ashley N. Hudson. UF 173955. Specimen found along ATV trail leading to compartment 13. This is a documented record from this parish; Dundee and Rossman (1989) referred to an unconfirmed museum record. Based on a recent genetic study, Bradley et al. (2013) suggest that this taxon should be referred to as *T. mexicana triunguis*. West Carroll Par.: AOR on Hwy 17 south of Pioneer (32.68716°N, 91.44994°W). 18 June 2006. Ashley N. Hudson. UF 173956. New parish record.

***TRACHEMYS SCRIPTA ELEGANS* (Red-eared Slider)**. Caldwell Par.: Boeuf Wildlife Management Area, near Cross Bayou (32.12465°N, 91.92355°W). 3 November 2013. Clayton R. Faidley. NLU 70736. New parish record. Shell remains.

SQUAMATA — LIZARDS

***ANOLIS SAGREI* (Brown Anole)**. Ouachita Par.: ULM greenhouse (32.52868°N, 92.07504°W). 26 September 2012. Matthew L. Reid. NLU 70737. A new parish record for this introduced species, the first in northern Louisiana. Found on a small ornamental pine tree in the ULM greenhouse that was acquired from the Home Depot garden center in Monroe earlier that day.

***HEMIDACTYLUS TURCICUS* (Mediterranean House Gecko)**. Grant Par.: Georgetown (31.76263°N, 92.38340°W). 7 June 2014. Charles D. Battaglia, Matthew L. Reid, and Matthew S. Herron. NLU 70738. New parish record. Fills in a distributional gap in northeastern Louisiana (Reid et al. 2014). Found on outside wall of the local post office. LaSalle Par.: 2134 East Oak St., Jena (31.68288°N, 92.12363°W). 7 June 2014. Matthew L. Reid, Charles D. Battaglia, and Matthew S. Herron. NLU 70739. New parish record. Fills a distributional gap in northeastern Louisiana (Reid et al. 2014). Found on outside wall of a gas station on Hwy 84.

***PLESTIODON FASCIATUS* (Common Five-lined Skink).** East Carroll Par.: Bayou Macon Wildlife Management Area (32.86321°N, 91.26924°W). 18 June 2006. Ashley N. Hudson. NLU 70740. New parish record. Fills in the only remaining parish in the state without a record.

SQUAMATA — SNAKES

***CROTALUS HORRIDUS* (Timber Rattlesnake).** Catahoula Par.: Sicily Island Hills Wildlife Management Area, (31.82597°N, 91.75369°W). 29 April 2012. ULM Advanced Herpetology Class. NLU 70741. New parish record. Helps fill gap in northeastern Louisiana. Coiled on the forest floor during a visual encounter survey.

***DIADOPHIS PUNCTATUS STICTOGENYS* (Mississippi Ring-necked Snake).** Tensas Par.: Buckhorn Wildlife Management Area, near Brushy Lake nature trail (32.04530°N, 91.36730°W). 5 April 2008. John L. Carr, Chase Holiday, Kody J. Chase, Thomas M. Pardue, and Samuel R. Holcomb. NLU 70742. New parish record.

***FARANCIA ABACURA* (Red-bellied Mudsnake).** Caldwell Par.: Boeuf Wildlife Management Area, AOR on Hwy 558 (31.97639°N, 91.95929°W). 29 June 2013. Clayton R. Faidley. NLU 70743. New parish record. Fills gap in northeastern Louisiana. East Carroll Par.: Bayou Macon Wildlife Management Area (32.85667°N, 91.27864°W). 31 March 2005. Ashley N. Hudson and Matthew D. Brown. NLU 70744. New parish record. Fills gap in northeastern Louisiana.

***LAMPROPELTIS TRIANGULUM* (Eastern Milksnake).** East Carroll Par.: Bayou Macon Wildlife Management Area (32.82068°N, 91.31544°W). 23 September 2005. Ashley N. Hudson. NLU 70745. New parish record. Recent genetic studies (Ruane et al. 2014) suggest that *L. t. amaura* be subsumed within *L. gentilis*. Based on the morphological characteristics (body ring count) and distribution outlined in Ruane et al. (2014), this specimen would appear to belong to the species *L. triangulum* and not *L. gentilis*.

***NERODIA CYCLOPION* (Mississippi Green Watersnake).** Catahoula Par.: Boeuf Wildlife Management Area, Enterprise Tract (31.93414°N, 91.88318°W). 22 April 2005. Matthew D. Brown and Andrew M. Perry. NLU 70746. New parish record.

***NERODIA FASCIATA CONFLUENS* (Broad-banded Watersnake).** Caldwell Par.: Boeuf Wildlife Management Area, DOR on Hwy 558 (31.97639°N, 91.95929°W). 29 June 2013. Clayton R. Faidley. NLU 70747. New parish record that fills in one of the remaining two Louisiana parishes without records.

***OPHEODRYS AESTIVUS* (Rough Greensnake).** East Carroll Par.: Bayou Macon Wildlife Management Area (32.85577°N, 91.30176°W). 25 May 2005. Ashley N. Hudson. NLU 70748. New parish record.

***PANTHEROPHIS GUTTATUS* (Red Cornsnake).** Catahoula Par.: Sicily Island Hills Wildlife Management Area (31.83222°N, 91.77099°W). 12 April 2008. John L. Carr and ULM herpetology class. NLU 70749 (egg). A new parish record from the flat bottomland of the northern branch of Big Creek. This record extends the range north of the Red River in the Mississippi Alluvial Valley. Female laid eggs in the lab (UF 173957), with one, non-viable egg kept as a voucher. The female and the live hatchlings were returned to the site.

***THAMNOPHIS PROXIMUS* (Western Ribbonsnake).** East Carroll Par.: Bayou Macon Wildlife Management Area (32.79276°N, 91.29892°W). 30 March 2005. Ashley N. Hudson and Matthew D. Brown. NLU 70750. New parish record.

Acknowledgments.—We thank N. Douglas for verifying all specimen identifications and K. L. Krysko for his help at FLMNH. We thank LDWF and UFWS for allowing us to collect (LNHP-01-060, LNHP-05-089, LNGP-06-022, LNGP-07-042, LNGP-08-043, WL-Research-2008-04, LNHP-09-059, LNHP-11-008, LNHP-12-049, WL-Research-2012-05, Special Use 42651-12-02, LNHP-13-051). We would also like to thank the students of the ULM classes that helped collect several of the specimens.

New County Distribution Records for Amphibians and Reptiles in Wisconsin

These new county records for Wisconsin were collected or verified subsequent to Casper (1996), as part of various projects for the Apostle Island National Lakeshore, Great Lakes Indian Fish and Wildlife Commission, HerpMapper (http://www.herpmapper.org), Lake Superior Binational Program, Milwaukee Public Museum, Ozaukee Washington Land Trust, U. S. Environmental Protection Agency Great Lakes Restoration Initiative, Wisconsin Coastal Management Program, Wisconsin DNR, and Wisconsin Herp Atlas (UWM Field Station Saukville, Wisconsin). The number of decimal places in coordinates reflects estimated precision. Standard English names follow Crother (2012).

CAUDATA — SALAMANDERS

***AMBYSTOMA LATERALE* (Blue-spotted Salamander).** Buffalo Co.: Trevino Bottoms (44.4273°N, 92.0618°W; WGS 84). 8 May 2011. Christopher E. Smith, Ben Lowe, Don Shepard. Verified by Thomas G. Anton. James Ford Bell Museum of Natural History, University of Minnesota, Minneapolis (JFBM Herp Photo 469). New county record within expected range, ca. 51 km SW of nearest published Dunn Co. record (Vogt 1981). Two observed under same piece of wood. Trempealeau Co.: Town 18 North, Range 8 West, Section 33 SW1/4 (quarter-section centroid 43.988°N, 91.346°W; WGS 84). 23 July 1998. Gary S. Casper. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 30299). New county record within expected range, ca. 3.5 km NNW of nearest published La Crosse Co. record (Casper 1996).

***AMBYSTOMA MACULATUM* (Spotted Salamander).** Douglas Co.: Douglas County Forest along E South Shore Grade (46.5223°N, 91.7716°W; WGS 84). 26 April 2011. Gary S. Casper, Stefanie M. Nadeau. Verified by Gregory Schneider. University of Michigan Museum of Zoology, Ann Arbor (UMMZ 243156). New county record extends range ca. 40 km NW from nearest published Bayfield Co. record (Vogt 1981). In log at roadside pond. Marinette Co.: 2.3 km N of Town Line Rd. on right side of Right-of-Way Rd. (45.270°N, 87.755°W; WGS 84). 27 September 1999. Dawn Dennis-Ruleau. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM Herp Photo 700). New county record within expected range, ca. 44.4 km ENE of nearest published Oconto Co. record (Casper 1996). Under board. Additional specimens collected in 2003 in western Marinette Co. (MPM 33394-5, 33401). Washington Co.: Silverbrook Camp (43.4046°N, 88.2186°W; WGS 84). 17 March 2012. Ron Gritt. Verified by Gregory Schneider. University of Michigan Museum of Zoology, Ann Arbor (UMMZ 243163-4). New county record. Ephemeral wetland in kettle valley with hardwood forest surround. New county record within expected range, ca. 15 km W of nearest published Ozaukee Co. record (Casper 1996).

GARY S. CASPER
UWM Field Station, 3095 Blue Goose Road, Saukville, Wisconsin 53080, USA; e-mail: gscasper@uwm.edu

***HEMIDACTYLIUM SCUTATUM* (Four-toed Salamander).** Columbia Co.: Wisconsin Dells (43.63°N, 89.77°W; WGS 84). 1967. Roy Fox. Verified by Steve Rogers. Carnegie Museum of Natural History, Pittsburgh, Pennsylvania (CM 62536). First county record, extends range ca. 7 km E from nearest published Sauk Co. record (Vogt 1981). Crawford Co.: N Branch of Copper Creek, Town 10 North, Range 5 West, Section 29 NW1/4 (43.318°N, 90.993°W; WGS 84). 15 September 1973. Sara Kauth. Verified by Thomas G. Anton. University of Wisconsin Zoological Museum, Madison (UWZM 24018). New county record, extends range ca. 25 km SE from nearest published Vernon Co. record (Vogt 1981). Old cow pasture with grasses and goldenrod, mature forest of white birch and poplar found under and in the rotted wood of a fallen trunk, very damp habitat. Douglas Co.: SE of jct of Anderson Rd. and Francis-Willard Rd. (46.473°N, 91.649°W; WGS 84). 17 June 1996. Gary S. Casper, Lacey Klucas, Noah Martinsen. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 27960). New county record, extends range ca. 24 km NW from nearest published Bayfield Co. record (Vogt 1981). Collected in shoreline clump of *Sphagnum magellanicium* (Brid.). Additional specimens collected ca. 8.5 km further W (46.444°N, 91.759°W; 46.438°N, 91.685°W; 46.4674°N, 91.7580°W; WGS 84), Milwaukee Public Museum (MPM 27961-3 respectively). Lincoln Co.: Ca. 1.31 km southeast of jct of County Rd. A and County Rd. H (45.4928°N, 89.5814°W; WGS 84). 29 April 2011. Gary S. Casper, Stefanie M. Nadeau. Verified by Gregory Schneider. University of Michigan Museum of Zoology, Ann Arbor (UMMZ 243203). New county record within expected range, ca. 23 km S of nearest published record in Oneida Co. (Casper 1996). Under rotted white birch log. Marinette Co.: Town 30 North, Range 23 East, Section 7 (section centroid 45.09°N, 87.75°W; WGS 84). 30 May 1997. Mike Rasmussen. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM Herp Photo 701). New county record within expected range, ca. 37.4 km NE of nearest published Oconto Co. record (Vogt 1981). Additional specimens collected in 2003 from NW Marinette Co. (45.5243°N, 88.3292°W; 45.3192°N, 88.2323°W; WGS 84), Milwaukee Public Museum (MPM 33381, 33413 respectively). Sawyer Co.: Flambeau River area, Town 39 North, Range 3 West, Section 33 SE1/4 of NE1/4 (45.821°N, 90.747°W; WGS 84). 22 June 2000. Kathryn Kirk. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 32903). New county record within expected range, ca. 49 km SSE from nearest published Ashland Co. record (Vogt 1981). Found in black spruce forest. Second specimen found near residence in Hayward (45.972°N, 91.431°W; WGS 84). 30 September 2001. Mike Heim. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 33279).

***NECTURUS MACULOSUS* (Mudpuppy).** Trempealeau Co.: Independence (44.36°N, 91.42°W; WGS 84). 1881. A. E. Van Name. Verified by Thomas G. Anton. Yale University, Peabody Museum of Natural History, New Haven, Connecticut (YPM 118). New county record within expected range, ca. 35 km N from nearest published La Crosse Co. record (Casper 1996). Additional specimens from same locality (YPM 31, 395).

***NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS* (Central Newt)**. La Crosse Co.: Town 17 North, Range 8 West, Section 5 SW1/4, along railroad. (43.974°N, 91.365°W; WGS 84). 27 July 1993. Robert Hay, Dan Nedrelo. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM Herp Photo 460). New county record, fills ca. 126 km gap in range, ca. 75.7 km SE of nearest published Buffalo Co. record (Casper 1996) and ca. 55.5 km NNW of nearest published Vernon Co. record (Vogt 1981). This specimen was previously published as a new Trempealeau Co. record (Casper 1996), but re-examination for georeferencing determined it was actually in La Crosse Co., based on matching the original locality description to aerial photography. The Trempealeau Co. occurrence is therefore suppressed. Marquette Co.: Ca. 2.8 km E of Germania on Eagle Rd. (43.889°N, 89.227°W; WGS 84). 12 May 1999. Matt Wright. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 30362). New county record, within ca. 85 km gap in expected range, ca. 38 km NW of nearest published Dodge Co. record (Vogt 1981). 30-40 observed in small pond. Oneida Co.: Ca. 619 m north of Oscar-Jenny Lake (45.6305°N, 89.6658°W; WGS 84). 23 March 2012. Robert Hay. Verified by Gregory Schneider. University of Michigan Museum of Zoology, Ann Arbor (UMMZ Herp Photo 1259-60). New county record within expected range, ca. 10 km NNE of nearest published Lincoln Co. record (Casper 1996). Wood Co.: 10 mi SE Stratford (44.67°N, 89.98°W; WGS 84). 29 June 1927. L. C. Stuart. Verified by Gregory Schneider. University of Michigan Museum of Zoology, Ann Arbor (UMMZ 64813-9). New county record within expected range, ca. 61 km N of nearest published Juneau Co. record (Vogt 1981).

ANURA — FROGS

***ACRIS BLANCHARDI* (Blanchard's Cricket Frog)**. Adams Co.: Ca. 8 km W of Briggsville in southeastern Adams Co. (43.65°N, 89.69°W; WGS 84). 22 September 1929. Francis M. Uhler. Verified by Thomas G. Anton. National Museum of Natural History, Smithsonian Institution (USNM 311739). New county record within expected range, ca. 25 km NW of nearest published Columbia Co. record (Vogt 1981). Green Lake Co.: Spaulding's Bridge, Town 16 North, Range 13 East, Section 2 (section centroid 43.89°N, 88.92°W; WGS 84). 14 September 1957. D. G. Dunlap. Verified by Thomas G. Anton. University of Nebraska State Museum, Lincoln (UNSM 22449). New county record within expected range, ca. 23.5 km WSW of nearest published Marquette Co. record (Vogt 1981). Trempealeau Co.: Town 18 North, Range 10 West, Section 2 SW1/4 (quarter section centroid 44.059°N, 91.546°W; WGS 84). 10 September 1965. R. Fassbender. Verified by Thomas G. Anton. University of Wisconsin Zoological Museum, Madison (UWZM 19038). New county record within expected range, ca. 33 km W of nearest published La Crosse Co. record (Vogt 1981).

***HYLA CHRYSOSCELIS* (Cope's Gray Treefrog)**. Jefferson Co.: Lost Lake, just W of Rock Lake (43.0824°N, 88.9462°W; WGS 84). 30 April 1997. Karen Etter Hale, Mary Nelesen. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM Herp Photo 658 with associated audio recording). New county record within expected range, ca. 21 km SE of nearest published Dane Co. record (Vogt 1981).

***HYLA VERSICOLOR* (Gray Treefrog)**. Door Co.: Bay Shore Bluff-lands State Natural Area (44.9489°N, 87.3758°W; WGS 84). 31 May 2014. Nancy Aten, Dan Collins. Verified by Gregory Schneider. University of Michigan Museum of Zoology, Ann Arbor (UMMZ Herp Photo 1261 with sonogram and digital audio recording). New county record within expected range, ca. 69 km NNE of nearest published Kewaunee Co. record (Vogt 1981). Full chorus calling from ephemeral pond in mixed northern hardwood forest, 0246 hr CST, ambient temperature 15.5°C.

***LITHOBATES CATESBEIANUS* (American Bullfrog)**. Grant Co.: N of Dubuque, Iowa, on Wisconsin side of Mississippi River (42.5733°N, 90.6597°W; WGS 84). 27 June 2008. Kyle Salzmann. Verified by Christopher E. Smith. James Ford Bell Museum of Natural History, University of Minnesota, Minneapolis (JFBM Herp Photo 470). New county record within expected range, ca. 88 km SSE of nearest published Crawford Co. record (Vogt 1981), 47 km NW of nearest published Jo Daviess Co., Illinois, record (Smith et al. 1999, AMNH 137397), and confirms prior published observational record from same area (Vogt 1981). Trempealeau Co.: Perrot State Park (44.02°N, 91.47°W; WGS 84). 11 September 1947. Strand and Edgren Stahlecker. Verified by Thomas G. Anton. Chicago Academy of Sciences, Chicago, Illinois (CHAS 19340, now housed at FMNH). New county record within expected range, ca. 34.7 km NW of nearest published La Crosse Co. record (Casper 1996).

***LITHOBATES PALUSTRIS* (Pickerel Frog)**. Fond du Lac Co.: Adjacent to campground at NE side of Mauthe Lake, Town 13 North, Range 19 East, Section 12 NE1/4 of SW1/4 of SW1/4 (43.6043°N, 88.1765°W; WGS 84). 5 May 2000. Deb Coblentz. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 32883). New county record, within ca. 100 km gap in expected range, ca. 31 km SSW of nearest published Sheboygan Co. record (Vogt 1981). From cold seeps. Jackson Co.: Black River Falls (44.30°N, 90.85°W; WGS 84). 4 June 1920. A. J. Poole. Verified by Thomas G. Anton. University of Wisconsin Zoological Museum, Madison (UWZM 3501). New county record within expected range, ca. 21 km SSW of nearest published Clark Co. record (Vogt 1981).

***LITHOBATES SYLVATICUS* (Wood Frog)**. Walworth Co.: Mallard Ridge Landfill ca. 5 km west of Delavan N side Hwy 11 (42.6468, 88.7191°W; WGS 84). 22 April 1996. Gary S. Casper. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM Herp Photo 538). New county record within expected range, ca. 37 km ENE of nearest published Rock Co. record (Vogt 1981). 18 egg masses photographed in ephemeral wetland.

***PSEUDACRIS CRUCIFER* (Spring Peeper)**. Green Lake Co.: White River Marsh, Town 17 North, Range 12 East, Section 21 (section centroid 43.93°N, 89.08°W; WGS 84). 17 April 1959. D. G. Dunlap. Verified by Thomas G. Anton. University of Nebraska State Museum, Lincoln (UNSM 22864). New county record within expected range, ca. 22 km SE of nearest published Waushara Co. record (Vogt 1981).

TESTUDINES — TURTLES

***APALONE MUTICA MUTICA* (Midland Smooth Softshell)**. La Crosse Co.: Mississippi River backwater approx. 0.4 km S of I-90 bridge (43.8564°N, 91.2713°W; WGS 84). 8 July 1999. Eric Kramer. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 33150). New county record within expected range, ca. 23 km SE of nearest published Trempealeau Co. record (Vogt 1981). One of two drowned in fish survey net. Supports additional unverified specimens collected in 1973 by M. A. Ewert from an

unspecified locality in the Mississippi River in La Crosse Co., Carnegie Museum of Natural History, Pittsburgh, Pennsylvania (CM 88440-74).

***APALONE SPINIFERA SPINIFERA* (Eastern Spiny Softshell).** Kenosha Co.: Powers Lake (42.55°N, 88.30°W; WGS 84). 17 May 2001. Rick Dauffenbach. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM Herp Photo 699). New county record within expected range, ca. 17 km S of nearest published Racine Co. record (Vogt 1981). One of two caught in fyke nets during fish surveys. Supports prior observational record in slough on S end of Paddock Lake (42.570°N, 88.102°W; WGS 84), 1987, Barbara Wolf; and from Elizabeth Lake (42.51°N, 88.27°W; WGS 84), 1989, Ken Mierzwa (GSC, unpubl. data). Ozaukee Co.: Lac du Cours Creek, tributary of Milwaukee River (43.1967°N, 87.9565°W; WGS 84). 31 May 2011. Luke Roffler. Verified by Christopher A. Phillips. Illinois Natural History Survey, University of Illinois, Champaign (INHS Herp Photo 2012h). New county record within expected range, ca. 31 km NNE of nearest published Milwaukee Co. record (Casper 1996). Photographed basking in small pond. Second photo from same site on 23 April 2012. Supports unverified specimen from Donges Bay (43.20 °N, 87.89°W; WGS 84), 1933, L. R. Taylor, Milwaukee Public Museum (MPM 2459), which is missing. Additional observation from River Island Park in Milwaukee River in Grafton ca. 14 km N of Lac du Cours Creek (43.3252°N, 87.9461°W; WGS 84) on 21 July 2012 by Phyllis McKenzie (GSC, unpubl. data). Price Co.: Jump River, Ogema Township (45.41°N, 90.66°W; WGS 84). Approx. 1995. Mike Lord. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM Herp Photo 704). New county record within expected range, ca. 53 km SE of nearest published Sawyer Co. record (Casper 1996). Sheboygan Co.: Sheboygan (43.75°N, 87.71°W; WGS 84). 23 September 1956. C. Benninghaus. Verified by Charles M. Dardia. Cornell University Museum of Vertebrates, Ithaca, New York (CU 11332). New county record adjacent to documented counties to south and west, ca. 58 km NE of nearest published Washington Co. record (Casper 1996). Skull only. Washington Co.: Big Cedar Lake, directly opposite Gonring Dr. boat launch (43.4022°N, 88.2523°W; WGS 84). 16 August 2010. Carcass from anonymous boaters photographed by Gary S. Casper. Verified by Christopher A. Phillips. Illinois Natural History Survey, University of Illinois, Champaign (INHS Herp Photo 2010q). New county record within expected range, ca. 40.3 km NNE of nearest published Waukesha Co. record (Casper 1996). Found washed up on shore with propeller wounds.

***CHRYSEMYS PICTA* (Painted Turtle).** Green Co.: near Sugar River, Town 3 North, Range 8 East, Section 14 (42.73°N, 89.52°W; WGS 84). 9 May 1998. Andrew H. Williams. Verified by Alan Resetar. Field Museum of Natural History, Chicago, Illinois (FMNH 270549). New county record within expected range, ca. 23 km S of nearest published Dane Co. record (Vogt 1981). Dead on road.

***GRAPTEMYS GEOGRAPHICA* (Northern Map Turtle).** Milwaukee Co.: Milwaukee, Milwaukee River on south side of old North Ave. dam (43.0579°N, 87.8947°W; WGS 84). 11 July 2007. Gary S. Casper. Verified by Christopher A. Phillips. Illinois Natural History Survey, University of Illinois, Champaign (INHS Herp Photo 2012m). First county record and first verified record for Milwaukee River system, ca. 127 km E of nearest published Dane Co. record (Vogt 1981). Three individuals basking. Possibly introduced in this urban area, with nearest known natural populations in the Wisconsin River (Vogt 1981) and Des Plains River, Illinois (Phillips et al. 1999). Additionally reported from the Milwaukee River at two Ozaukee Co. locations in 2013, suggesting the species is established in this river beyond Milwaukee Co. (Kristina M. Kroening, personal communication July 2014). The earliest known reports for Milwaukee Co. are from the Wildlife ARC, which received two injured specimens on 20 June 1987 for rehabilitation (*fide* Dawn Reshel) from Town 8 North, Range 21 East, Sections 23 and 35, ca. 3.5 km from the Milwaukee River (GSC, unpubl. data). Pierce Co.: Diamond Bluff (44.65°N, 92.62°W; WGS 84). 5 August 1899. Collector unknown. Verified by Christopher E. Smith. James Ford Bell Museum of Natural History, University of Minnesota, Minneapolis (JFBM R490). First county record, ca. 38 km SSE of nearest published St. Croix Co. record (Vogt 1981). Supports observational records reported by Vogt (1981).

***GRAPTEMYS PSEUDOGEOGRAPHICA PSEUDOGEOGRAPHICA* (Northern False Map Turtle).** Buffalo Co.: On main channel of Mississippi River across from W Newton Chute (44.287°N, 91.918°W; WGS 84). 12 July 2011. Christopher E. Smith. Verified by Thomas G. Anton. James Ford Bell Museum of Natural History, University of Minnesota, Minneapolis (JFBM Herp Photo 472). First county record within expected range, ca. 30.5 km SE of nearest published Pepin Co. record (Vogt 1981). Captured in turtle trap. Chippewa Co.: Chippewa River, 3.2 km S of Jim Falls (45.021°N, 91.295°W; WGS 84). 12 July 1973. Richard C. Vogt. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 6836). First county record, extends range ca. 33 km NE of nearest published Eau Claire Co. record (Casper 1996).

SQUAMATA — LIZARDS

***PLESTIODON SEPTENTRIONALIS SEPTENTRIONALIS* (Northern Prairie Skink).** Buffalo Co.: Trevino Bottoms (44.4274°N, 92.0607°W; WGS 84). 14 September 2014. Erica Hoaglund, Ben Lowe, Chris Smith, Jon Murray. Verified by Thomas G. Anton. James Ford Bell Museum of Natural History, University of Minnesota, Minneapolis (JFBM Herp Photo 473). First county and southern-most Wisconsin record, extends range ca. 51 km SW of nearest published Dunn Co. record (Vogt 1981). Under railroad tie along railroad right of way. Second specimen photographed ca. 402 m to W (44.4279°N, 92.0657°W; WGS 84) on same date, James Ford Bell Museum of Natural History, University of Minnesota, Minneapolis (JFBM Photo 474).

SQUAMATA — SNAKES

***COLUBER CONSTRICTOR* (North American Racer).** Lafayette Co.: Town 4 North, Range 5 East, Section 26 NW1/4 (quarter section centroid 42.795°N, 89.873°W; WGS 84). 22 October 1963. Collector unknown. Verified by Thomas G. Anton. University of Wisconsin Zoological Museum, Madison (UWZM 17362). First county record, extends range ca. 35 km SSE from nearest published Iowa Co. record (Vogt 1981), and ca. 62 km NE from nearest published Jo Daviess Co., Illinois, record (Phillips et al. 1999).

***DIADOPHIS PUNCTATUS EDWARDSII* (Northern Ring-necked Snake).** Manitowoc Co.: Two Rivers (44.15°N, 87.57°W; WGS 84). Date unknown. Collector unknown. Verified by Chris R. Feldman. University of Nevada, Museum of Biology, Reno (UNR 6343). First county record, fills ca. 104 km gap in range along Lake Michigan, ca. 53 km from nearest published Sheboygan Co. record to south (Vogt 1981) and ca. 55 km from nearest published

Brown Co. record to north (Casper 1996). Oconto Co.: Bear Paw Scout Camp (estimated location 45.19°N, 88.40°W; WGS 84). 17 July 1956. P. Litchfield. Verified by Steve Rogers. Carnegie Museum of Natural History, Pittsburgh, Pennsylvania (CM 36867). First county record, extends range ca. 32 km ESE from nearest published Langlade Co. record (Casper 1996).

***LAMPROPELTIS TRIANGULUM* (Eastern Milksnake)**. Green Lake Co.: Snake Creek (43.87°N, 89.00°W; WGS 84). 19 June 1959. D. G. Dunlap. Verified by Thomas G. Anton. University of Nebraska State Museum, Lincoln (UNSM 16472). New county record within expected range, ca. 19 km SE of nearest published Marquette Co. record (Vogt 1981). Supports prior observational record from Boy Scout camp on S shore of Green Lake (43.80°N, 89.00°W; WGS 84) by William Hilsenhoff in the 1940s, ca. 7.4 km to S (GSC, unpubl. data).

***NERODIA SIPEDON SIPEDON* (Northern Watersnake)**. Chippewa Co.: 9.7 km from Eau Claire (44.89°N, 91.47°W; WGS 84). 17 July 1927. L. C. Stuart. Verified by Gregory Schneider. University of Michigan Museum of Zoology, Ann Arbor (UMMZ 64740). First county record within expected range, ca. 30 km WNW from nearest published Eau Claire Co. record (Vogt 1981). Second specimen found on Hwy M W of 160th St. (45.2326°N, 91.3575°W; WGS 84). 20 May 2003. Richard A. Sajdak. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 33346). Polk Co.: 19.3 km E of Luck at Big Round Lake (45.52°N, 92.30°W; WGS 84). 4 August 1946. M. J. Toews. Verified by Christopher E. Smith. James Ford Bell Museum of Natural History, University of Minnesota, Minneapolis (JFBM R1294). First county record within expected range, ca. 28 km S from nearest published Burnett Co. record (Vogt 1981). Confirms earlier Vogt (1981) observation from Polk Co. Second specimen collected from same lake on 6 July 1940 is unverified, American Museum of Natural History, New York (AMNH 64101). St. Croix Co.: specific locality unknown (county centroid 45.03°N, 92.45°W; WGS 84). 30 May 1939. R. Anderson. Verified by Christopher E. Smith. James Ford Bell Museum of Natural History, University of Minnesota, Minneapolis (JFBM R1024). First county record within expected range, county centroid is ca. 42 km NE from nearest published Pierce Co. record (Casper 1996), and county line ca. 14 km N of same.

***OPHEODRYS VERNALIS* (Smooth Greensnake)**. Ashland Co.: Long Island, Apostle Islands National Lakeshore, between lighthouse and pier (46.7289°N, 90.7848°W; WGS 84). 27 May 2001. Brian J. Halstead. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 33088). First county record within expected range, ca. 42 km NE from nearest published Bayfield Co. record (Vogt 1981). Under board near pile of boards/driftwood in bluegrass. La Crosse Co.: On County Hwy DE, Section 7 SE1/4 of NE1/4 (43.9634°N, 91.0154°W; WGS 84). 21 July 1990. J. Kerkman. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 23519). First county record within expected range, ca. 22 km W from nearest published Monroe Co. record (Casper 1996). Road kill, upland oak and aspen forest with cultivated farmland nearby. Vernon Co.: Wildcat Mountain State Park, just off Hwy 33 on road to lower picnic area (43.695°N, 90.577°W; WGS 84). 28 July 1990. Karen Teed. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 23475). First county record within expected range, ca. 25.3 km NW from nearest published Richland Co. record (Casper 1996). Road kill.

***PANTHEROPHIS VULPINUS* (Eastern Foxsnake)**. Ashland Co.: Residence along Luttinen Rd., Marengo (46.395°N, 90.847°W; WGS 84). 10 October 2007. Gus Smith. Verified by Christopher A. Phillips. Illinois Natural History Survey, University of Illinois, Champaign (INHS Herp Photo 2011j). New county record, ca. 50 km ENE from nearest published record in SW Bayfield Co. (Casper 1996). Photographed in yard. Second specimen found at jct of Bass Lake and North York roads (46.3666°N, 90.7800°W; WGS 84). 2 June 2011. Thomas G. Anton, David Mauger. Verified by Alan Resetar. Field Museum of Natural History, Chicago, Illinois (FMNH 282467). Male with 39 dorsal blotches. Also observed gravid female with 38 dorsal body blotches, under board on top of wood chip pile in old gravel quarry. Surrounding habitat grassy fields and second growth northern hardwood forest. Price Co.: 1.6 km S of Fiefield on Hwy 13 (45.868°N, 90.428°W; WGS 84). 23 May 1978. M. R. Niblick. Verified by D. S. McLeod. University of Nebraska State Museum, Lincoln (UNSM 16104). New county record within expected range, ca. 69 km NE from nearest published record in Rusk Co. (Casper 1996). Second specimen from Co. Rd. C, 0.2 km south of RR tracks just within limits of Village of Prentice (45.537°N, 90.289°W; WGS 84). June 1999. Mike Spagnolo. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 30385).

***REGINA SEPTEMVITTATA* (Queensnake)**. Green Co.: Tributary of Sugar River (42.6°N, 89.4°W; WGS 84). May 2005. Aaron Garland. Verified by Christopher E. Smith. James Ford Bell Museum of Natural History, University of Minnesota, Minneapolis (JFBM Herp Photo 471). New county record, extends range ca. 49.5 km W from nearest published Wisconsin record in Rock Co. (Kapfer et al. 2009), and 51.5 km NNW from nearest published Illinois record in Winnebago Co. (Phillips et al. 1999). Location generalized due to Endangered Species status. Sunning in rock fill of dam spillway. Supports ca. 1960 observation by George Bachay on Sugar River ca. 9 km NNW of this record (GSC, unpubl. data).

***SISTRURUS CATENATUS* (Eastern Massasauga)**. Portage Co.: specific locality unknown (county centroid 44.47°N, 89.50°W; WGS 84). 1 October 1967. J. Small. Verified by Steve Rogers. Carnegie Museum of Natural History, Pittsburgh, Pennsylvania (CM 70492). New county record, extends range at least 25 km NE from nearest published record in Juneau Co. (Vogt 1981). Dried skin with rattle.

***STORERIA DEKAYI* (Dekay's Brownsnake)**. Green Lake Co.: White River Wash Area, Town 17 North, Range 12 East, Section 32 (section centroid 43.90°N, 89.10°W; WGS 84). 30 May 1974. Richard C. Vogt. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 7934). New county record within expected range, ca. 38 km NNW from nearest published record in Dodge Co. (Vogt 1981). St. Croix Co.: specific locality unknown (county centroid 45.03°N, 92.45°W; WGS 84). 2 July 1939. R. Anderson. Verified by Christopher E. Smith. James Ford Bell Museum of Natural History, University of Minnesota, Minneapolis (JFBM R1019). New county record within expected range, county centroid is ca. 26 km NW from nearest published record in Pierce Co. (Casper 1996), and county border is ca. 0.8 km N from same. Washburn Co.: Hwy M, 14.5 km E and 4.0 km S of Spooner (45.800°N, 91.725°W; WGS 84). 18 August 1971. W. G. Reeder. Verified by Thomas G. Anton. University of Wisconsin Zoological Museum, Madison (UWZM 24065). New county record within expected range, ca. 50 km SE from nearest published record in Burnett Co. (Vogt 1981).

***STORERIA OCCIPITOMACULATA OCCIPITOMACULATA* (Northern Red-bellied Snake)**. Menominee Co.: Big Eddy Falls (44.965°N, 88.635°W; WGS 84). 19 June 1925. T. E. B. Pope. Verified by Thomas G. Anton. Milwaukee Public Museum (MPM 1903). New county record within expected range, ca. 16 km NNE from nearest published record in Shawano Co. (Vogt 1981).

***THAMNOPHIS PROXIMUS PROXIMUS* (Orange-striped Ribbonsnake)**. Jefferson Co.: 6.4 km W of Eagle (42.88°N, 88.55°W; WGS 84). 23 July 1963. R. G. Pladies. Verified by Thomas G. Anton. Brigham Young University, Monte L. Bean Life Science Museum, Provo, Utah (BYU 40420). New county record. Extends range ca. 110 km SE from nearest Sauk Co. records (Vogt 1981).

***THAMNOPHIS RADIX* (Plains Gartersnake)**. Lafayette Co.: specific locality unknown (county centroid 42.66°N, 90.13°W; WGS 84). 22 October 1963. Unknown. Verified by Thomas G. Anton. University of Wisconsin Zoological Museum, Madison (UWZM 17284). New county record. Second specimen from Lafayette / Iowa Co. line ca. 100 m E of bridge crossing Pecatonica River (42.8119°N, 90.2574°W; WGS 84). July 1995. Brick M. Fevold. Verified by Thomas G. Anton. University of Wisconsin Zoological Museum, Madison (UWZM 23900). Road kill. These records extend range ca. 35 km S and 48 km W from nearest published records in Vogt (1981). Sauk Co.: 4 mi SE of Reedsburg. (43.49°N, 89.95°W; WGS 84). 15 September 1963. D. Bray. Verified by Thomas G. Anton. University of Wisconsin Zoological Museum, Madison (UWZM 17277). New county record, extends range ca. 32 km W from nearest published Columbia Co. record (Vogt 1981).

***THAMNOPHIS SAURITUS SEPTENTRIONALIS* (Northern Ribbonsnake)**. Columbia Co.: Gibraltar Rock, Lodi (43.34°N, 89.60°W; WGS 84). 12 October 2014. Lester Doyle. Verified by Jace W. Robinson. University of Michigan Museum of Zoology, Ann Arbor (UMMZ Photo 1262-4). New county record, ca. 35 km S of nearest published Adams Co. record (Casper 1997). Locality generalized due to Wisconsin Endangered Species status. Door Co.: Peninsula State Park, found on road. (45.14°N, 87.21°W; WGS 84). 5 June 2008. Nicholas J. Meiers. Verified by Gregory Schneider. University of Michigan Museum of Zoology, Ann Arbor (UMMZ Photo 1257-8). New county record, extending range ca. 71 km E from nearest published record in Marinette Co. across Green Bay (Vogt 1981). Confirms observation reported from same location in 1963 by George J. Knudsen (GSC, unpubl. data). Locality generalized due to Wisconsin Endangered Species status.

Acknowledgments.—I thank the many people who make the effort to document herp distributions through the collecting of voucher specimens and photographs. The efforts of the Wisconsin Herp Atlas and HerpMapper are especially appreciated for encouraging proper scientific documentation. Collecting by the author was performed under Wisconsin DNR and Apostle Islands National Lakeshore Scientific Collecting Permits. Funding was provided in part by the Apostle Islands National Lakeshore (Bayfield, Wisconsin), National Park Service Great Lakes Network Office (Ashland, Wisconsin), National Fish and Wildlife Foundation Sustain Our Great Lakes Program (to the Ozaukee Washington Land Trust, West Bend, Wisconsin, and to Lakehead University, Thunder Bay, Ontario), U.S. Environmental Protection Agency Great Lakes Restoration Initiative (to the Great Lakes Indian Fish and Wildlife Commission, Odanah, Wisconsin; and to Ozaukee County Planning and Parks, Port Washington, Wisconsin), Wisconsin Coastal Management Grant Program (to Ozaukee County Planning and Parks), and Wisconsin DNR. I greatly appreciate the following folks for assisting with specimen deposition and verifications: Thomas G. Anton (FMNH), Christopher Austin (Louisiana State University), Henry L. Bart (Tulane University), Julia Colby (MPM), Brian I. Crother (Southeastern Louisiana University), Charles M. Dardia (CU), Thomas C. Erdman (Richter Museum of Natural History, University of Wisconsin, Green Bay), Chris R. Feldman (UNR), Laura A. Halverson Monahan (UWZM), Thomas Labedz (UNSM), Christopher A. Phillips (INHS), James Poindexter II (USNM), Alan Resetar (FMNH), Jace W. Robinson (Harper College, Palatine, Illinois), Steve Rogers (CM), Christopher E. Smith (HerpMapper), Gregory Schneider (UMMZ), Kenneth A. Tighe (USNM), Richard C. Vogt (Instituto Nacional de Pesquisas da Amazônia, Manaus, Brazil), Jens Vindum (California Academy of Sciences, San Francisco), Danielle S. Wasserman (Southeastern Louisiana University), and Gregory J. Watkins-Colwell (YPM). Finally, for facilitating funding, field work, and general encouragement, I thank Scott Posner (Chequamegon Nicollet National Forest); Carmen R. Hardin, Robert Hay, William Smith and Richard Staffen (Wisconsin DNR); Joan Elias, William Route, and Julie Van Stappen (National Park Service Great Lakes Network Office); Shawn Graff (Ozaukee Washington Land Trust); Jonathan Gilbert and Ann McCammon-Soltis (Great Lakes Indian Fish and Wildlife Commission); Ryne and Jenny Rutherford (Biophilia LLC); and Andrew Struck (Ozaukee County Planning and Parks).

Distributional Records for Amphibians and Reptiles from Wisconsin, USA

The following 32 county records either fill distribution gaps, or expand the known range of amphibian and reptile species native to Wisconsin beyond Vogt (1981), Casper (1996), and the many records that have been published since (e.g., Casper 1997, 1999). These records were obtained through field observations vouchered with photographs, through cross-referencing specimen collection databases, and through physical searches of specimen collections. Further documentation of the locality records described herein that are supported only by photographic vouchers or by very old specimens is desired, ideally by appropriate voucher specimens.

Several of these county records are based on old specimens that did not always include the specific location (other than county), date of collection (other than year), or additional contextual information. Although these records might be questionable, we have included them because they are supported by voucher specimens. Furthermore, they provide historical information relevant to upper Midwestern herpetology and could have important implications for future research and conservation endeavors. We also provide additional context for several of the more questionable old specimens. We do not further comment on old specimens that simply fill gaps for the known range of a species and instead focus on those that result in more substantial extensions to currently documented distributions. We also generally do not further comment on old specimens that represent range extensions into counties immediately adjacent to those with records supported by vouchers. Additional investigation into the locations associated with these questionable or old records is warranted and welcomed.

CAUDATA — SALAMANDERS

***AMBYSTOMA LATERALE* (Blue-spotted Salamander).** Green Co.: Town of Avon (T1N R9E, Section 13). 31 May 2008. Jeffrey Lorch. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015l photo voucher). Found in floodplain forest habitat. Iowa Co.: Village of Arena (T8N R5E, Section 9 NE1/4). 24 April 2010. Jeffrey Lorch. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015m, photo voucher). Found under log in floodplain forest near ephemeral pond. This voucher is corroborated by numerous additional observations of *A. laterale* at this location by Joshua Kapfer, and voucher photographs taken at a different location by Jeffrey Lorch (INHS 2015n, T8N, R4E, Section 20) on 16 October 2010 (verified by Robert Hay). Jefferson Co.: Village of Cambridge (T6N R13E, Section 17). 2 May 2008. Jeffrey Lorch. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015v, photo voucher). Eight individuals found under logs in woodlot adjacent to a shallow pond and lake. This record is supported by additional observations at another location (INHS 2015w; T5N R16E, Section 25) on 2 May 2008 by Jeffrey Lorch (verified by Robert Hay). Rock Co.: Town of Avon (T1N R10E, Section 28). 21 April 2007. Jeffrey Lorch. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015ad, photo voucher). Seven individuals found under bark or logs in floodplain forest. This observation is corroborated by a voucher photograph taken at another location (INHS 2015ae, T1N R10E, Section 18) by Jeffrey Lorch on 21 April 2007 (verified by Robert Hay).

***AMBYSTOMA MACULATUM* (Spotted Salamander).** Calumet Co.: Town of Stockbridge (T18N R18E, Section 12). 26 September 2010. Jeffrey Lorch. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015d, photo voucher). One juvenile found under a rock. Dodge Co.: Town of Mayville (T11N R16E, Section 1). 9 April 2011. Jeffrey Lorch and Corey Raimond. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015g, photo voucher). Racine Co.: "Racine, Wisc" is the only location information accompanying these specimens. Exact collection date unknown, but according to museum ledger information, this specimen was collected by S.F. Baird and entered into the collection on 2 August 1858. Verified by Kenneth Tighe. Specimen found in the National Museum of Natural History collection (USNM 3938). Five additional specimens accompanied by a similar lack of contextual data are housed in the National Museum of Natural History (USNM 270087–270091). S. F. Baird, or Spencer Fullerton Baird, was a former curator at the National Museum of Natural History. Baird traveled to Racine in 1853 where he, Jared P. Kirtland, and Philo R. Hoy collected numerous specimens (Deiss 1985). The group did not restrict their collecting to Racine County (Schorger 1944) and it is unclear why at least some of

the specimens collected at this time were not accessioned until 1858. Many herpetological specimens collected by Hoy that currently reside in various collections lack detailed contextual information. Furthermore, others have suggested that some of Hoy's specimens were wrongfully attributed to Racine (where he lived) instead of where the specimens were actually collected (Vogt 1981). For example, Hoy included several eastern salamander species in his "Catalogue of the cold-blooded vertebrates of Wisconsin" (Hoy 1883) that might have actually been collected in Ohio (Vogt 1981). It is plausible that Hoy retained Wisconsin specimens collected during Baird's 1853 visit, which were accidentally inter-mixed with his Ohio specimens, and later sent to USNM incorrectly labeled as originating in Racine County. Despite these potential issues, suitable habitat for *A. maculatum* would have existed in Racine County in the 1850s (Curtis 1959). Hoy specifically mentions that this species was found in Racine (Hoy 1883), although he did not report specimen numbers. A reliable record, supported by a voucher specimen in the Milwaukee Public Museum (MPM 2470) exists for Milwaukee County (Casper 1996), which is immediately north of Racine County. It is also vouchered just across the Wisconsin-Illinois border in nearby Lake, Cook, and Will counties (Anton 1999; Phillips et al. 1999). For these reasons it is probable that the specimen is labeled accurately, and this species existed historically in Racine County. The current status of *A. maculatum* in Racine County, however, is unknown.

***HEMIDACTYLIUM SCUTATUM* (Four-toed Salamander).** Iowa Co.: Village of Ridgeway (T6N R4E, Section 10). 18 May 2008. Jeffrey Lorch. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015o, photo voucher). An adult on a nest under a clump of moss in a wooded area near the base of a spring seepage. This is further corroborated by other observations of this species in Iowa County by Jeffrey Lorch on 16 May 2009 (INHS 2015q) at a different location (T7N R1E, Section 18; verified by Robert Hay). Price Co.: Chequamegon National Forest (T39N R3E, Section 26). 20 May 2011. Jeffrey Lorch and Corey Raimond. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015ab, photo voucher). An adult female with eggs under sphagnum moss on a log overhanging a pool in a cedar-hemlock-white pine swamp.

***NOTOPHTHALMUS VIRIDESCENS* (Eastern Newt).** Columbia Co.: Village of Rio (T11N R10E, Section 14). 24 March 2007. Jeffrey Lorch. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015e, photo voucher). Two terrestrial phase adults: one crossing road at 1 pm, the other captured while dipnetting within a small cattail/sedge pond within oak opening. Richland Co.: Village of Lone Rock (T8N R2E, Section 11). 31 August 2007. Jeffrey Lorch and Corey Raimond. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015ac, photo voucher). One terrestrial phase adult under a railroad tie near a trestle running through a slough of the Wisconsin River.

***PLETHODON CINEREUS* (Eastern Red-backed Salamander).** Calumet Co.: Town of Stockbridge (T18N R19E, Section 7). 26 September 2010. Jeffrey Lorch. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015c, photo voucher). Ten individuals captured under rocks and logs in dry mesic woods. Dane Co.: museum database lists "Madison" as the location and includes the following coordinates: 43.0731°N, 89.4012°W; WGS 84 (which is roughly in the middle of the University of Wisconsin-Madison campus). No collection date or collector provided. Verified by Kenneth Tighe. National Museum of Natural History collection (USNM 10903). An additional specimen apparently collected at this location (USNM 10902) is now lost. It is uncertain if coordinates accompanying this record represent the location of collection or the location of Madison, Wisconsin where the specimen may have resided prior to being transferred to USNM. Although there is a report of *P. cinereus* approximately 45 km to the northwest of Madison (Lange 2014), the nearest confirmed records are at least 150 km away. Furthermore, central Dane County was historically oak savanna—a dry habitat type that is not typically associated with this species. Thus, it seems unlikely that the specimen was collected in Dane County, but future surveys might shed additional light on the subject. Menominee Co.: Census Designated Place of Keshana, Menominee Native American Reservation (no additional specific locality data provided). 18 May 1951. R. Nero. Verified by Chris Phillips. University of Wisconsin-Madison Zoology Museum (UWZM 17592). Six individuals were in the jar associated with this number. Racine Co.: original museum ledger entry lists "Racine Wis". According to museum ledger, this specimen was collected by "Bailey" and accessioned on 2 August 1858. Verified by Kenneth Tighe. National Museum of Natural History (USNM 3788). According to associated notes, multiple specimens were housed under this catalogue number and "7 of 8" remained at the National Museum of Natural History and re-catalogued as USNM 276576–276582 in January 1987. It is unclear who "Bailey" was, but that this specimen was accessioned on the same date as USNM 3938 could suggest that it was part of Hoy's collection or was obtained during the 1853 collection event involving Baird (see *Ambystoma maculatu*m account for Racine County). Hoy does not mention that this species occurred near Racine (Hoy 1883), but it is possible that he confused *P. cinereus* for another species that he erroneously considered present (e.g., *Eurycea bislineata*). Suitable habitat for *P. cinereus* would have occurred near Racine in the mid 1800s (Curtis 1959). This coupled with the new record for this species from Washington County (see below) and the fact that it is vouchered in nearby Cook County, Illinois (Anton 1999; Phillips et al. 1999), indicates that at one time *P. cinereus* distribution followed the corridor of mesic forest along the western shore of Lake Michigan, as suggested by Casper (1996). For these reasons, we believe this record may be historically accurate, but the current status of *P. cinereus* in Racine County is unknown. Washington Co.: Kettle Moraine State Forest-Northern Unit (T12N, R19E, Section 14). 4 May 2008. Jeffrey Lorch. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015ak, photo voucher). Seven more individuals found in general vicinity on 13 July 2008 by Jeffrey Lorch (INHS 2015al, verified by Robert Hay).

ANURA — FROGS

***LITHOBATES PALUSTRIS* (Pickerel Frog).** Adams Co.: Township of Douglas (specific location information accompanying specimen is "ca. 5 mi W of" the community of Briggsville). 22 September 1929. Collector not recorded. Verified by Kenneth Tighe. National Museum of Natural History collection (USNM 312213). Additional specimens reportedly collected on the same date from the same location are USNM 312214–312216. The location associated with this record is somewhat suspect, given the fact that "ca. 5 mi W" of Briggsville is very close to the border with Marquette County (Briggsville is actually located just over the border in Marquette County). Yet this species is documented in most of the immediately adjacent counties, which supports its

presence in Adams County. Further survey work to confirm the presence of *L. palustris* in this county is warranted.

***LITHOBATES SEPTENTRIONALIS* (Mink Frog)**. Marathon Co.: City of Marathon (T28N R05E Section 1). 10 June 1949. Sr. M. Joyce. Verified by Robert Hay. Milwaukee Public Museum (MPM 3474).

***LITHOBATES SYLVATICUS* (Wood Frog)**. Racine Co.: original museum ledger entry lists "Racine Wis" and museum database includes the following specific location: 42.7264°N, 87.8056°W; WGS 84. 31 July 1858. P. Hoy. Verified by Kenneth Tighe. National Museum of Natural History collection (USNM 3385). It is uncertain if coordinates accompanying this record represent the location of collection or the location of Racine, Wisconsin. According to associated notes, 12 specimens were housed under this number and 1–3 of them were sent to the University of Michigan Museum of Zoology (UMMZ 3865). The reliability of specimens donated to USNM by Hoy is described in greater detail in the *Ambystoma maculatum* account for Racine County. The habitat preferences of *L. sylvaticus* are similar to those of *A. maculatum* and such habitat existed near Racine in 1858 (Curtis 1959). Furthermore, many voucher specimens of *L. sylvaticus* exist in the Milwaukee Public Museum that came from Milwaukee County, which is immediately north of Racine County (e.g., MPM 1263, 1287–1363, etc.), although these were collected in the early 1900s. It has also been documented across the Wisconsin-Illinois border in Lake, Cook, and Will Counties (Anton 1999; Phillips et al. 1999). Thus, it is likely that this record is historically accurate, but the current status of *L. sylvaticus* in Racine County is unknown.

TESTUDINES — TURTLES

***APALONE SPINIFERA* (Spiny Softshell)**. Waupaca Co.: 44.633054°N, 88.634074°W. 6 June 2000. Erik Wild and Joel Ernst. Verified by Peter Zani. University of Wisconsin-Stevens Point Museum of Natural History (UWSP 3803). Backwater-bay of Wolf River at public boat landing off Hwy 156, laying on surface of floating vegetation in about 1-m deep water.

***GRAPTEMYS OUACHITENSIS* (Southern Map Turtle)**. Portage Co.: specific locality unknown. Date of collection unknown. Richard Vogt, Alan Jaslow, Bruce Hellmich. Verified by Robert Hay. Carnegie Museum of Natural History collection (CM 95113). This represents a substantial northward extension in the documented range of this species. It bypasses Juneau, Adams, and likely Wood counties (where *G. ouachitensis* has not yet been documented) and creates a new gap in its known range in Wisconsin. However, the same distributional pattern is documented for a related riverine species (*G. pseudogeographica*), which has also been vouchered in Portage County (Carnegie Museum of Natural History, CM 95112; Vogt 1981). The Wisconsin River runs through Juneau, Adams, and Wood counties, creating an obvious connection between Portage County and documented populations in Sauk and Columbia counties to the south. Therefore, it is reasonable that this species' range historically extended into Portage County, although modern anthropogenic modifications to the river along its course (e.g., dams) may have restricted movement. For example, substantial dams along the Wisconsin River exist near the city of Wisconsin Rapids (Wood County), which could have fragmented populations to the north and south. It is possible that a lack of recent *G. ouachitensis* documentation in more northern counties (such as Portage) reflects the slow decline or extirpation of previously isolated populations.

***GRAPTEMYS PSEUDOGEOGRAPHICA* (False Map Turtle)**. Pierce Co.: Bay City (specific locality given as "Lake Pepin"). 10 June 1973. Michael Ewert. Verified by Tony Gamble. Carnegie Museum of Natural History (CM 87555).

***TERRAPENE ORNATA* (Ornate Box Turtle)**. Jackson Co.: Only specific location information accompanying specimen is "near Hatfield," Wisconsin. According to museum records, the specimen was collected "before the 1950's". Charles F. Sindelar. Verified by Thomas Erdman. University of Wisconsin-Green Bay, Richter Museum of Natural History (R451). The validity of the location associated with this specimen is difficult to assess. The area from which this specimen was purportedly collected is approximately 100 km north of the currently recognized range limit for the species in Wisconsin (Casper 1996; Vogt 1981). The vague information regarding the location of its collection could potentially associate it with several habitat types. The unincorporated census-designated place of Hatfield is within the vicinity of three major plant community-types in Wisconsin: oak savanna, pine barrens/savanna, and conifer-hardwood forest (Curtis 1959). The other known populations of *T. ornata* in Wisconsin are almost exclusively associated with oak savanna and prairie (Vogt 1981). While they are not found in the conifer-hardwood forest community or documented in the pine savanna community, the latter is dry, open, and sandy like oak savanna. Thus, oak savanna and perhaps pine savanna could have potentially provided suitable habitat for *T. ornata* at this location. However, it seems unusual that the species would exist in an isolated pocket so far north of its known range, particularly when suitable habitat was historically common between the location of this record and the known southern populations (Curtis 1959). Yet, the area along the Black River in Jackson County is known to contain other species with more southern affinities (Wisconsin Department of Natural Resources 2005), which may have contributed to the presence of an isolated *T. ornata* population in Jackson County. This record may support that the historic range of *T. ornata* in Wisconsin was once larger, and this species perhaps occupied the suitable habitat up to Jackson County, but has undergone a more recent range contraction. Given that box turtles are easily collected and transported by humans, perhaps the Jackson County specimen is the result of a translocation. Regardless, given the sensitive nature of this species in Wisconsin (i.e., currently considered endangered), this record may be important for future conservation endeavors.

SQUAMATA — LIZARDS

***PLESTIODON FASCIATUS* (Common Five-lined Skink)**. Marquette Co.: Village of Coloma (T17N R9E, Section 3). 3 July 2010. Jeffrey Lorch. Verified by Robert Hay. Illinois Natural History Survey (INH 2015aa, photo voucher). One juvenile found under woody debris in pine-oak barrens. Waupaca Co.: No specific location given, aside from county. 10 July 1955. F. Iwen and Stanley Wellso. Verified by Chris Phillips. University of Wisconsin-Madison Zoology Museum (UWZM 14718).

SQUAMATA — SNAKES

***DIADOPHIS PUNCTATUS* (Ring-necked Snake)**. Vernon Co.: 43.536042°N, 91.151527°W; WGS 84. 11 June 2006. Joshua Kapfer. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2014z, photo voucher). Several individuals (one gravid female and two mature males) found on a partially wooded slope under a rock. Adjacent habitat was pasture and a small creek.

***HETERODON PLATIRHINOS* (Eastern Hog-nosed Snake)**. Green Co.: No specific location given aside from Albany, Wisconsin. Specimen collected in "fall" 1960. Lloyd France. Verified by Chris Phillips. University of Wisconsin-Madison Zoology Museum (UWZM 22788). Jefferson Co.: Kettle Moraine State Forest-Southern Unit (T5N R16E, Section 33). 7 June 2006. Jeffrey Lorch. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015x, photo voucher). Two juveniles found under rotting logs in open sandy area in transmission line right-of-way. La Crosse Co.: Community of Mindoro (T18N R5W, Section 19). 23 June 2010. Kate Olson. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015h, photo voucher). One adult found crossing a residential lawn.

***LAMPROPELTIS TRIANGULUM* (Eastern Milksnake)**. Trempealeau Co.: City of Galesville (44.099791°N, 91.352259°W; WGS 84). 13 July 2014. Patrick Stoner. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2014w, photo voucher). Numerous individuals found on the same day at this location.

***STORERIA DEKAYI* (Dekay's Brownsnake)**. Adams Co.: T16N R5E, Section 23. 4 July 2008. Jeffrey Lorch. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015b, photo voucher). Eight individuals found under logs in a small opening in oak barrens.

***STORERIA OCCIPITOMACULATA* (Red-bellied Snake)**. Lafayette Co.: Town of Fayette (T4N R4E, Section 34). 6 October 2007. Jeffrey Lorch. Verified by Robert Hay. Illinois Natural History Survey (INHS 2015z, photo voucher). Approximately 30 individuals seen both alive and as roadkill on a gravel road separating a mesic and wet-mesic field from upland woodlots.

Acknowledgments.—We appreciate the assistance of collection managers and curatorial staff who assisted with acquisition and verification of specimens, including J. Colby (Milwaukee Public Museum), C. Phillips (Illinois Natural History Survey), T. Erdman (University of Wisconsin-Green Bay, Richter Museum of Natural History), L. Monahan (University of Wisconsin-Madison, Zoology Museum), K. Tighe and J. Jacobs (National Museum of Natural History), and S. Rogers (Carnegie Museum of Natural History). R. Hay, P. Zani, and T. Gamble also assisted with verification of specimen identification or background information. Furthermore, R. Staffen, R. Paloski, and M. Turner provided important data on recent reports for several species. A. Badje helped photograph specimens for confirmation of identification.

One Hundred Two New County Records for Amphibians and Reptiles in Alabama, USA

The diversity and distribution of Alabama's amphibians and reptiles was first examined comprehensively in Mount's (1975) regional field guide. In subsequent years, however, less effort was invested into general inventory of the state's herpetofauna. Interest in generating a thorough documentation of Alabama's herpetofauna has re-emerged in the last decade. In particular, an impressive effort by Graham et al. (2009) documented 101 new county records for the state, and their inspiring efforts appear to have spurred other significant projects, such as inventories in Tuskegee National Forest (Graham et al. 2012), Pike County (Burchill and Diamond 2014), and northern Alabama (Sutton et al. 2014). Despite the renewed interst, few counties within Alabama have been sampled extensively, and large distributional gaps still remain for the majority of species in the state.

In anticipation of a forthcoming revision to Mount (1975), we sought to further the spirit of our Auburn colleagues by compiling a series of new county records of amphibians and reptiles throughout Alabama. We accrued novel observations and specimens during research activities, nocturnal road-cruising surveys, class field trips, and targeted collecting trips to under-sampled areas. Here we report 102 new county records for Alabama, which includes at least one new county record for 52 species. Records were vouchered as specimens or digital photographs and were deposited into the Herpetological Collections of the Auburn University Museum of Natural History (AUM, AUMO, AHAP-D, AHAP-C, AHAP-P). All records were verified by Craig Guyer. The datum for all GPS coordinates is WGS 84. Standard English names follow Crother (2012).

CAUDATA — SALAMANDERS

***AMBYSTOMA MACULATUM* (Spotted Salamander)**. USA: ALABAMA: Madison Co.: Monte Sano State Park Bankhead parkway (34.74690°N, 86.50720°W). 23 April 2010. J. Stiles, S. Stiles. AUM 38876.

***AMBYSTOMA TIGRINUM* (Eastern Tiger Salamander)**. USA: ALABAMA: DeKalb Co.: Farm pond, 200 m S of CR 624 (34.50206°N, 85.60568°W). 12 May 2012. J. Stiles, S. Stiles. AUM 39673.

***AMPHIUMA MEANS* (Two-toed Amphiuma)**. USA: ALABAMA: Elmore Co.: Tumkeehatchee Creek (32.51725°N, 86.01073°W). 2 September 2001. J. C. Godwin, J. G. Godwin. AUM 36383. Escambia Co.: Solon Dixon Center, Rope Swing, Cypress Oxbow Pond (31.18907°N, 86.70925°W). 4 October 2013. J. Stiles, S. Stiles. AUM 40455. Geneva Co.: Spring Creek at Spring Creek Rd. (31.03273°N, 85.70049°W). 4 October 2013. D. Werneke. AUM 40447. Mount (1975) reports a literature record for the county; this animal represents the first vouchered individual.

***EURYCEA GUTTOLINEATA* (Three-lined Salamander)**. USA: ALABAMA: Chambers Co.: Off of Highway 50 at intersection with Little Chatahospee Creek (32.84134 °N, 85.4918°W). 16 March 2015. R. Birkhead. AUM 41035. Collected from a leaf pack in the creek's floodplain.

***GYRINOPHILUS PORPHYRITICUS* (Spring Salamander)**. USA: ALABAMA: Franklin Co.: Rock Bridge Canyon Park, spring run (34.36270°N, 87.93321°W). 23 August 2014. J. Stiles, S. Stiles. AUM 40821.

***PSEUDOTRITON RUBER RUBER* (Northern Red Salamander)**. USA: ALABAMA: Tallapoosa Co.: Tributary to Timbergut Creek, east of Patterson Rd, 0.48 km N of intersection with Cowpens Rd (33.05020°N, 85.78149°W). 10 May 2011. D. Werneke, J. Armbruster, T. Mosely, C. Ray, T. Hess, C. Ames. AUM 39760.

***PSEUDOTRITON RUBER VIOSCAI* (Southern Red Salamander)**. USA: ALABAMA: Covington Co.: Conecuh National Forest, Pond Creek at CR 24 (31.10167°N, 86.53900°W). 22 May 2013. B. Folt, J. Goessling. AUM 40223–40224, 40230.

***PLETHODON GLUTINOSUS* (Northern Slimy Salamander)**. USA: ALABAMA: Randolph Co.: Off of Highway 77, 0.56 road km SE from intersection with CR 15 (33.14067°N, 85.61987°W). Found under logs on hardwood slope. 16 March 2015. R. Birkhead. AUM 41036–41037.

***PLETHODON GROBMANI* (Southeastern Slimy Salamander)**. USA: ALABAMA: Bullock Co.: The Wehle Tract (32.02917°N, 85.47493°W). 26 April 2014. B. Folt, M. Miller, C. Guyer. AUM 40582.

***PLETHODON WEBSTERI* (Webster's Salamander)**. USA: ALABAMA: Randolph Co.: In ravine 0.07 air km SW of intersection of CR 15, CR 889, and railroad tracks (33.19665°N, 85.57873°W). Found by raking leaf litter on hardwood slope. 16 March 2015. R. Birkhead. AUM 41044.

***SIREN INTERMEDIA* (Lesser Siren)**. USA: ALABAMA: Autauga Co.: CR 29, 3.22 road km S of CR 14, wetland next to New Jericho Missionary Baptist Church (32.40363°N, 86.51600°W). 13 May 2014. D. Laurencio, S. Belford. AUM 40645. Houston Co.: Irwin Mill Creek, immediately west of AL 95 (31.00504°N, 85.04117°W). 4 March 2014. D. Laurencio, S. Belford. AUM 40489.

ANURA — FROGS

***ACRIS CREPITANS* (Eastern Cricket Frog)**. USA: ALABAMA: Autauga Co.: 3.22 road km S of CR 14 on CR 29, wetland next to New Jericho Missionary Baptist Church (32.40363°N, 86.51600°W). 31 April 2014. D. Laurencio, A. T. Harris, R. Burgenden. AUM 40597. Cherokee Co.: Captured along small tributary of Terrapin Creek along CR 33 between Sanford Springs and Frog Mountain (34.01887°N, 85.57391°W). 26 August 2014. R. Birkhead. AUM 40755. Lowndes Co.: 0.32 road km S of CR 40 on Lake Berry Rd (32.32101°N, 86.53706°W). 14 May 2014. D. Laurencio, S. Belford. AUM 40654–56. Randolph Co.: Captured along Cornhouse Creek at Highway 431 bridge (33.23896°N, 85.44194°W). 27 August 2014. R. Birkhead. AUM 40756. Tallapoosa Co.: The Coon Creek Forever Wild Tract (32.59779°N, 85.87508°W). 5 November 2011. J. Goessling, B. Folt, I. E. P. Turner. AUM 39724–39727, 39730.

***ACRIS GRYLLUS* (Southern Cricket Frog)**. USA: ALABAMA: Autauga Co.: south of CR 14 on CR 29, wetland next to New Jericho Missionary Baptist Church (32.40363°N, 86.51600°W). 13 May 2014. D. Laurencio, S. Belford. AUM 40639–40640. Franklin Co.: Spring outflow at Rock Bridge Canyon (34.36269°N, 87.93300°W). 23 August 2014. J. Stiles, S. Stiles. AUM 40767. Lamar Co.: Collected from swamp 1.1 km S of Fernbank Rd. (CR 12) on AL 17 (33.58066°N, 88.08423°W). 5 May 2014. R. Birkhead. AUM 40621.

***ANAXYRUS AMERICANUS* (American Toad)**. USA: ALABAMA: Lauderdale Co.: CR 9, 0.4 km W of intersection with CR 41 (34.88779°N, 87.74103°W). 12 March 2015. J. Stiles. AUM 41021. Tallapoosa Co.: Ca. 5 km S of Highway 280 on CR 89 (32.74032°N, 85.65764°W). 10 January 2012. B. Folt, J. Goessling. AUM 39778.

***ANAXYRUS TERRESTRIS* (Southern Toad)**. USA: ALABAMA: Elmore Co.: 3.54 road km E of CR 8 on CR 4 (32.45090°N, 86.15934°W). 30 April 2014. D. Laurencio, A. T. Harris, R. Burgenden. AUM 40591. Mount (1975) lists only hybrids between *A. fowleri* x *A. terrestris* for Elmore Co.

***GASTROPHRYNE CAROLINENSIS* (Eastern Narrow-mouthed Toad)**. USA: ALABAMA: Lowndes Co.: 3.1 road km W of CR 37 on CR 54 (32.32413°N, 86.539027°W). 14 May 2014. D. Laurencio, S. Belford. AUM 40666.

***HYLA AVIVOCA* (Bird-voiced Treefrog)**. USA: ALABAMA: Autauga Co.: 3.22 road km S of CR 14 on CR 29, wetland next to New Jericho Missionary Baptist Church (32.40363°N, 86.51600°W). 13 May 2014. D. Laurencio, S. Belford. AUM 40635–36. Elmore Co.: Poundstone Lake (32.43751°N, 86.11422°W). 30 April 2014. D. Laurencio, A. T. Harris, R. Burgenden. AUM 40594–95. Geneva Co.: CR 4 (31.03893°N, 85.922275°W). 21 May 2012. B. Folt. AHAP-C 0014. Numerous males calling in a roadside beaver pond.

***HYLA CHRYSOSCELIS* (Cope's Gray Treefrog)**. USA: ALABAMA: Autauga Co.: 3.21 road km S of CR 14 on CR 29, in a wetland immediately north of New Jericho Missionary Baptist Church (32.40363°N, 86.51600°W). 13 May 2014. D. Laurencio, S. Belford. AUM 40637-38. Coffee Co.: 10 m N of CR 484 on CR 473 (31.20898°N, 86.14799°W). 14 April 2014. J. Goessling. AUM 40536. Elmore Co.: 3.54 road km E of CR 8 on CR 4 (32.45090°N, 86.15934°W). 30 April 2014. D. Laurencio, A. T. Harris, R. Burgenden. AUM 40592.

***HYLA CINEREA* (Green Treefrog)**. USA: ALABAMA: Autauga Co.: 3.22 road km S of CR 14 on CR 29, wetland next to New Jericho Missionary Baptist Church (32.40363°N, 86.51600°W). 13 May 2014. D. Laurencio, S. Belford. AUM 40633–34. Geneva Co.: CR 4 (31.047017°N, 85.899119°W). 21 May 2012. B. Folt. AHAP-C 13. Numerous males were recorded calling from a roadside pond at night.

***LITHOBATES CATESBEIANUS* (American Bullfrog)**. Cherokee Co.: Captured in drying beaver pond on Sandy creek where it crosses CR18 at Sandy Springs (34.072956°N, 85.499496°W). 26 August 2014. R. Birkhead. AUM 40757. Lamar Co.: State Highway 17 at intersection with Fernbank Rd. (33.58182°N, 88.08466°W). 3 March 2015. B. Folt, J. Goessling, C. Guyer. AUM 40965.

***LITHOBATES CLAMITANS* (Green Frog)**. USA: ALABAMA: Barbour Co.: Tributary to Leak Creek, immediately north of where creek crosses Old Batesville Rd (31.93325°N, 85.32658°W). 7 February 2015. C. Kemp, B. Folt. AUM 40937. Cherokee Co.: Captured in drying beaver pond on Sandy creek where it crosses CR 18 at Sandy Springs (34.072956°N, 85.499496°W). 26 August 2014. R. Birkhead. AUM 40758. Covington Co.: Conecuh National Forest (31.10860°N, 86.57620°W). 10 July 2014. J. Stiles, S. Stiles. AUM 40711. Franklin Co.: Hulsey Branch near Bear Creek and Highway 187 (34.35879°N, 87.90043°N). 23 August 2014. J. Stiles, S. Stiles. AUM 40771. Geneva Co.: 1.5 km W of AL 52 on AL 54 (31.11450°N, 86.13235°N). 14 April 2014. J. Goessling, J. Stiles, S. Stiles. AUM 40534. Dead on road (DOR). Randolph Co.: Wolfpen Creek, 0.37 air km SE of intersection of where Wolfpen Creek intersects CR 843. (33.13972°N, 85.62504°W). 16 March 2015. R. Birkhead. AUM 41038. Tallapoosa Co.: The Coon Creek Tract (32.60301°N, 85.8631°W). 5 November 2011. B. Folt, J. Goessling, I. E. P. Turner. AUM 39729.

***LITHOBATES PALUSTRIS* (Pickerel Frog)**. USA: ALABAMA: Franklin Co.: Piney Point Recreation Area (34.39191°N, 87.98483°W). 11 March 2015. J. Stiles. AUM 41014.

***LITHOBATES SPHENOCEPHALUS* (Southern Leopard Frog)**. USA: ALABAMA: Autauga Co.: Spring feeding into Bear Creek, south of bridge at Highway 14 (32.43086°N, 86.57449°W). 1 June 2013. B. Folt, C. Montross. AUM 40236. Adult collected in swampy

floodplain. Covington Co.: Conecuh National Forest (31.12014°N, 86.59860°W). 31 January 2013. J. Stiles, S. Stiles. AUM 40713. Elmore Co.: 0.32 road km E of Laprade Rd (32.45321°N, 86.06511°W). 30 April 2014. D. Laurencio, A. T. Harris, R. Burgenden. AUM 40594–95. Geneva Co.: CR 4 (31.03779°N, 85.95413°W). 21 May 2012. B. Folt. AHAP-D 568. Found DOR while night driving. Mount (1975) reports a literature record for the county; this animal represents the first vouchered individual. Marion Co.: Collected from small borrow pit Alabama Rd. 19 between Hamilton and Vina (34.28519°N, 88.06445°W). 5 May 2014. R. Birkhead. AUM 40625. Pickens Co.: Liberty Rd./CR 75, 0.64 km S of intersection with McDill Rd. (33.49297°N, 88.17159°W). 3 March 2015. B. Folt, J. Goessling, C. Guyer. AUM 40964.

***PSEUDACRIS BRACHYPHONA* (Mountain Chorus Frog)**. USA: ALABAMA: Chambers Co.: 1.3 road km E of Chambers CR 11 on Chambers CR 22 (32.780611°N, 85.54050°W). 20 January 2012. J. Goessling, D. Laurencio. AUM 39781-82. Franklin Co.: Piney Point Recreation Area (34.39232°N, 87.98689°W). 11 March 2015. J. Stiles. AUM 40990. Lamar Co.: Ditch north of Fernbank Rd., 0.80 km west of intersection with Pleasant Ridge Rd. (33.57900°N, 88.10063°W). 3 March 2015. J. Goessling, B. Folt, C. Guyer. AUM 40966.

***PSEUDACRIS CRUCIFER* (Spring Peeper)**. USA: ALABAMA: Autauga Co.: 3.2 road km S of CR 14 on CR 29, wetland next to New Jericho Missionary Baptist Church (32.40363°N, 86.51600°W). 31 April 2014. D. Laurencio, A. T. Harris, R. Burgenden. AUM 40605, 40667. Elmore Co.: Forever Wild property near Kent (32.63076°N, 85.94417°W). 17 January 2012. B. Folt, J. Goessling. AHAP-D 534. Found AOR. Lauderdale Co.: CR 16, just west of Cypress Creek (34.85831°N, 87.73693°W). 12 March 2015. J. Stiles. AUM 41006.

***PSEUDACRIS FERIARUM* (Upland Chorus Frog)**. USA: ALABAMA: Houston Co.: 0.16 road km W of Springhill Church Rd. (CR 101) on Turnpike Rd. (31.11909°N, 85.11150°W). 4 March 2014. D. Laurencio, S. Belford. AUM 40495. Calling male. Lowndes Co.: cattle field immediately south of intersection of CR 40 and Robinson Switch Rd. (32.32259°N, 86.616407°W). 10 January 2013. B. Folt. AUM 40120. Calling male.

***SCAPHIOPUS HOLBROOKII* (Eastern Spadefoot)**. USA: ALABAMA: Geneva Co.: CR 4 (31.03742°N, 8595763°W). 21 May 2012. B. Folt. AUM 39866.

CROCODYLIA — CRODODILIANS

***ALLIGATOR MISSISSIPIENSIS* (American Alligator)**. USA: ALABAMA: Geneva Co.: Pea River (30.99758°N, 86.01225°W). 24 May 2012. B. Folt, J. Godwin, J. Lovich, J. Ennen. AHAP-D 572.

TESTUDINES — TURTLES

***APALONE SPINIFERA* (Spiny Softshell)**. USA: ALABAMA: Lauderdale Co.: McFarland Park (34.78483°N, 87.68995°W). 31 July 2014. J. Stiles, S. Stiles. AHAP-D 939.

***CHELYDRA SERPENTINA* (Snapping Turtle)**. USA: ALABAMA: Colbert Co.: 0.8 road km S of Flatwoods Rd on Frankfort Rd (34.62778°N, 87.77964°W). 3 May 2014. J. Stiles, S. Stiles. AUMO 4818. Gravid adult female found DOR. Eggs preserved as AUM 40610. Geneva Co.: Pea River (31.21252°N, 86.12341°W). 23 May 2012. B. Folt, J. Godwin, J. Lovich, J. Ennen, B. Kreiser. AHAP-D 570. Found swimming in shallow water near a sandy shoreline. Lamar Co.: Found DOR 1.1 km S of Fernbank Rd (CR 12) on AL 17 (33.58066°N, 88.08423°W). 5 May 2014. R. Birkhead. AUMO 4852.

***GRAPTEMYS PULCHRA* (Alabama Map Turtle)**. USA: ALABAMA: Coosa Co.: Coosa Wildlife Management Area (32.84785°N, 86.39541°W). 15 July 2012. B. Folt, I. E. P. Turner. AHAP-D 594; AUMO 4622. Skull and shell found in a creek.

***KINOSTERNON SUBRUBRUM* (Eastern Mud Turtle)**. USA: ALABAMA: Geneva Co.: 150 m W of Maloy Rd. where AL 54 crosses Panther Creek (31.10956°N, 86.14525°W). 27 April 2014. J. Goessling. AUM 40571. DOR.

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle)**. USA: ALABAMA: Autauga Co.: 3.2 road km S of CR 14 on CR 29, ditch next to New Jericho Missionary Baptist Church (32.40390°N, 86.51631°W). 31 April 2014. D. Laurencio, A. T. Harris, R. Burgenden. AUM 40600.

***TERRAPENE CAROLINA* (Eastern Box Turtle)**. USA: ALABAMA: Cherokee Co.: 0.47 road km N of CR 308 on CR 33 just south of McFrey Crossroads (33.98892°N, 85.57805°W). 26 August 2014. R. Birkhead. AUM–O 4819. DOR.

***TRACHEMYS SCRIPTA* (Pond Slider)**. USA: ALABAMA: Autauga Co.: 0.23 road km W of Buena Vista Blvd on CR 4 (32.42391°N, 86.45240°W). 13 May 2014. D. Laurencio, S. Belford. AUM 40662. Conecuh Co.: SR 55, 0.5 road km past County Highway 107 (31.51186°N, 86.70181°W). 17 June 2012. B. Folt. AHAP-D 575. Intact shell found on road. Franklin Co.: Sloss Lake (34.48587°N, 87.70807°W). 23 August 2014. J. Stiles, S. Stiles. AHAP-D 944.

SQUAMATA — LIZARDS

***ANOLIS CAROLINENSIS* (Green Anole)**. USA: ALABAMA: Coosa Co.: CR 29 (32.95209°N, 86.33030°W). 15 July 2012. B. Folt, I. E. P. Turner. AUM 39945. Mount (1975) reports a literature record, but this specimen is the first voucher. Sumter Co.: Sumter County Recreation Association Park (32.5538°N, 88.19995°W). 3 March 2014. J. Goessling, B. Folt, C. Guyer. AUM 40957. Mount (1975) reports a literature record, but this specimen is the first voucher.

***SCINCELLA LATERALIS* (Little Brown Skink)**. USA: ALABAMA: Bullock Co.: Wehle Tract, on dirt road north of pond next to Wehle Office (32.03563°N, 85.47168°W). 26 April 2014. C. Guyer, M. Miller, B. Folt. AUM 40573.

***PLESTIODON FASCIATUS* (Common Five-lined Skink)**. USA: ALABAMA: Bullock Co.: Wehle Tract (32.03504°N, 85.47283°W). 26 April 2014. C. Guyer, M. Miller, B. Folt. AUM 40574. Randolph Co.: 0.92 road km E of CR 32 on Wedowee Creek View Dr. (33.34292°N, 85.51219°W). 19 October 2013. S. Abate. AUM 40454. Sumter Co.: floodplain east of CR 17, 0.64 km N of bridge over Interstate Highway 59 (32.52749°N, 88.29874°W). 3 March 2015. C. Guyer, J. Goessling, B. Folt. AUM 40958.

SQUAMATA — SNAKES

***AGKISTRODON CONTORTRIX* (Copperhead)**. USA: ALABAMA: Chambers Co.: State Route 77 (33.05693°N, 85.43458°W). 9 September 2012. B. Folt. AHAP-D 622. DOR adult. Geneva Co.: Eulon Mills

Rd., 200 m W of Old County Rd. (31.11520°N, 86.18915°W). 23 April 2014. J. Goessling. AUM 40565. Monroe Co.: CR 47, ca. 25 km W of Greeneville (31.820972°N, 86.951778°W). 23 March 2012. J. Goessling, M. Wines. AHAP-D 544.

***AGKISTRODON PISCIVORUS* (Cottonmouth)**. USA: ALABAMA: Franklin Co.: Small creek by Prices Bridge (34.31207°N, 87.82220°W). 23 August 2014. J. Stiles, S. Stiles. AUM 40876. Lowndes Co.: Between 3.2–4.0 km NE of Braggs pine/swamp (32.06945°N, 86.77163°W). 2 May 1996. M. Bailey. AUM 33789.

***CARPHOPHIS AMOENUS* (Common Wormsnake)**. USA: ALABAMA: Chambers Co.: Off of Highway 50, at its intersection with Little Chatahospee Creek (32.84074°N, 85.49256°W). 16 March 2015. R. Birkhead. AUM 41033. Found by raking leaf litter on a hardwood-covered slope above the creek's floodplain.

***COLUBER CONSTRICTOR* (North American Racer)**. USA: ALABAMA: Dallas Co.: 0.64 road km W of CR 25 on Highway 80 (mile marker 70) (32.43997°N, 87.25317°W). 21 April 2012. D. Laurencio. AUM 39904.

***CROTALUS HORRIDUS* (Timber Rattlesnake)**. USA: ALABAMA: Clay Co.: Rock Pile Creek, off Fuller Rd., 1.13 road km N of White Plains Rd. (33.147303°N, 85.78384°W). 10 July 2012. I.E.P. Turner. AHAP-D 607. Sub-adult found crossing a dried-up stream bed. Coosa Co.: State Highway 22 (32.88303°N, 86.05581°W). 15 July 2012. B. Folt, I. E. P. Turner. AHAP-D 593. Henry Co.: State Highway 95, 0.48 road km S of CR 204 (31.65066°N, 85.21984°W). 19 August 2013. C. Guyer. AUM 40408.

***HETERODON PLATIRHINOS* (Eastern Hog-nosed Snake)**. USA: ALABAMA: Butler Co.: State Route 10 (Pineapple Highway) ca. 18 km W of Greeneville (31.828056°N, 86.78425°W). 23 March 2012. J. Goessling, M. Wines. AHAP-D 543. Melanistic individual found DOR. Cleburne Co.: CR 522, ca. 0.32 km NW of intersection with CR 523 (33.70555°N, 85.62835°W). 16 September 2014. J. Stiles, S. Stiles. AHAP-D 958. Coffee Co.: AL 52, 0.58 km SE of CR 490 (31.19320°N, 86.15690°W). 23 April 2014. J. Goessling. AHAP-D 798. Geneva Co.: Geneva State Forest, Forest Area Rd., ca. 0.5 km W of Harrison Rd (31.11974°N, 86.16515°W). 14 April 2014. J. Goessling. AUM 40540.

***LAMPROPELTIS ELAPSOIDES* (Scarlet Kingsnake)**. USA: ALABAMA: Colbert Co.: Dirt road west of Coon Dog Cemetery Rd. (34.62390°N, 87.97257°W). 7 May 2010. S. Stiles. AUM 40183.

***NERODIA SIPEDON* (Common Watersnake)**. USA: ALABAMA: Randolph Co.: Cornhouse creek at Highway 431 bridge (33.23896°N, 85.44194°W). 27 August 2014. R. Birkhead. AUM 40753-54. Found beneath flat rocks right at edge of water.

***REGINA SEPTEMVITTATA* (Queensnake)**. USA: ALABAMA: Escambia Co.: Wing Rd. bridge over Blackwater Creek (31.02881°N, 86.704706°W). 1 September 2013. J. Goessling, B. Folt, C. Murray, M. Cook, S. Johnson, J. Zeyl, C. Guyer. AHAP-D 914. DOR; ravaged by ants, but identified by ventral scale color pattern.

***OPHEODRYS AESTIVUS* (Rough Greensnake)**. USA: ALABAMA: Geneva Co.: Geneva State Forest, Mud Hole Rd., ca. 100 m W of Harrison Rd. (31.16129°N, 86.18737°W). 27 April 2014. J. Goessling. AHAP-D 799. Monroe Co.: Along train track on west side of tunnel (31.665359° N, 87.229261° W). 23 April 1999. R. Birkhead. AHAP-D 858.

***PANTHEROPHIS SPILOIDES* (Gray Ratsnake)**. USA: ALABAMA: Elmore Co.: Forever Wild Property (32.63430°N, 85.93947°W). 22 March 2012. B. Folt, J. Goessling. AHAP-D 537. Found within the door of an abandoned refrigerator. Franklin Co.: 0.9 km S of Jackson Rd. on AL 247 (34.5079.0°N, 88.01897°W). 8 May 2014. R. Birkhead. AUM 40626.

***TANTILLA CORONATA* (Southeastern Crowned Snake)**. USA: ALABAMA: Elmore Co.: Forever Wild Property, north of Kent (32.633083°N, 85.941306°W). 10 March 2012. J. Goessling, S. Goetz, M. Miller. AUM 39812.

***THAMNOPHIS SAURITUS* (Eastern Ribbonsnake)**. USA: ALABAMA: Tallapoosa Co.: 1.7 road km NW of CR 98 on Piedmont Drive/Mayton Street (32.82212°N, 85.65006°W). 13 April 2012. D. Laurencio. AUM 39833.

***THAMNOPHIS SIRTALIS* (Common Gartersnake)**. USA: ALABAMA: Geneva Co.: Geneva State Forest, Harrison Rd., ca. 100 m W of Mud Hole Rd (31.15813°N, 86.18046°W). 27 April 2014. J. Goessling. AHAP-D 800.

***SISTRURUS MILIARIUS* (Pygmy Rattlesnake)**. USA: ALABAMA: Escambia Co.: CR 11, south of intersection with Highway 15/29 (31.11183°N, 86.76351°W). 31 August 2013. B. Folt, C. Guyer, C. Murray, J. Zeyl, J. Stiles, M. Cook, S. Johnson. AUM 40387.

Acknowledgments.—We thank C. Ward for reviewing the manuscript and those who contributed records reported here. Recognition is also deserved to Craig Guyer, who verified the records and encouraged this project. War eagle! Museum specimens were collected with permission from the Alabama Department of Conservation and Natural Resources (Scientific Permit 7587) and under the guidelines of Auburn University IACUC #2010–1827.

New Geographic Distributional Records of Amphibians and Reptiles in Georgia, USA

The publication *Amphibians and Reptiles of Georgia* (Jensen et al. 2008) represents the most recent collection of distributional records for the state. Despite this robust data set, numerous gaps remain for common and rare species at both the county and projected statewide range levels. Reported herein are 20 novel county distributional records including valuable range extension data on several cryptic species, 19 of which represent the upper Piedmont, Ridge and Valley, and Blue Ridge physiographic provinces. Unless otherwise noted, all records consist of vouchered digital photographs located in the Georgia Museum of Natural History (GMNH). Species identifications were verified by Nikole Castleberry unless indicated otherwise. All coordinates are based on datum WGS 84. Standard English names follow Crother (2012).

CAUDATA — SALAMANDERS

***AMBYSTOMA MACULATUM* (Spotted Salamander).** White Co.: 3.00 km NW of Sautee Nacoochee, just NW of the intersection of Bean Creek Road and Gold Valley Road (34.708709°N, 83.685396°W). 28 February 2011. B. Hudson, Z. Seymour, and N. Dean. GMNH 50908. Numerous adults (>15) observed in several ephemeral pools during a rain event at night. Depressions were formed from previous gold mining activities. Five adults were captured using a dip net for photo vouchers.

***AMBYSTOMA TALPOIDEUM* (Mole Salamander).** Banks Co.: 4.20 km SE of Gillsville, 1.50 km SW of the intersection of Carson Segars Road and Mize Cemetary Road (34.299602°N, 83.588992°W). 9 March 2014. B. Hudson and K. McEntire. GMNH 50897. A single adult flipped under a rock on the edge of a beaver controlled wetland, just N of county reservoir 21. Polk Co.: 8.00 km NW of Cedartown, 1.00 km NW of the intersection of Cave Springs Road and Kings Bridge Road (34.063883°N, 85.316451°W). 4 January 2015. B. Hudson and J. Oguni. GMNH 50906. Two terrestrial adults found with spotlights at night and captured using a dip net in an ephemeral pool created in the early 1900's for iron ore production. Two additional paedomorphic adults were captured by using a dip net at another ephemeral pool just W of the first pool.

***AMBYSTOMA TIGRINUM* (Eastern Tiger Salamander).** Bartow Co.: 8.60 km N of Taylorsville, 0.15 km NW of the intersection of Taylorsville Macedonia Road and Ore Mine Road (34.163990°N, 84.986994°W). 20 May 2013. E. Rush, B. Wilson, J. Oguni, and B. Hudson. GMNH 50903. A single adult found after pushing out the stump of a pecan tree in the yard of a private residence.

***EURYCEA GUTTOLINEATA* (Three-lined Salamander).** Fannin Co.: 12.6 km NW of Blue Ridge, 1.85 km SW of the intersection of Lebanon Road and Madola Road (34.927550°N, 84.438567°W). 23 June 2010. B. D. Hudson and T. Stratmann. Verified by Elizabeth McGhee. GMNH 50131. A single adult found surface active on the bank of a small creek.

***HEMIDACTYLIUM SCUTATUM* (Four-toed Salamander).** Banks Co.: 5.30 km S of Alto, 0.40 km W of the intersection of Beaver Swamp Road and Lost Corner Road on Wilson Shoals Wildlife Management Area (34.419847°N, 83.564944°W). 25 March 2014. B. Hudson and D. Duff. GMNH 50898. Two adults flipped under logs on the edge of a small ephemeral pool located just inside a unit burned a few weeks prior to the observations.

TESTUDINES — TURTLES

***CHELYDRA SERPENTINA* (Snapping Turtle).** Pickens Co.: Camp Dobbs Road, 0.2 km E of intersection with Pleasant Union Road (34.384633°N, 84.500327°W). 8 June 2014. Z. Felix. GMNH 50916. A single adult found alive on road.

SQUAMATA — LIZARDS

***PLESTIODON LATICEPS* (Broad-headed Skink).** Stephens Co.: 4.80 km N of Toccoa, 0.85 km NW of the intersection of Anderson Road and Highview Road (34.620621°N, 83.331799°W). 22 May 2014. B. Hudson and D. Duff. GMNH 50907. A single adult flipped under a rock on a rocky, south-facing, forested hillside.

***SCINCELLA LATERALIS* (Little Brown Skink).** White Co.: 6.60 km NE of Helen, N of the parking lot for Anna Ruby Falls, at the end of Anna Ruby Falls Road (34.758468°N, 83.710207°W). 9 April 2011. B. Hudson. GMNH 50909. A single adult found basking on top of leaf litter near Anna Ruby Falls Trail.

SQUAMATA — SNAKES

***COLUBER FLAGELLUM* (Coachwhip)**. Clay Co.: 7.95 km NE of Fort Gaines, just W of the intersection of Coleman Road and Bethel Church Road (31.641718°N, 84.972493°W). 16 April 2005. B. Hudson. GMNH 50902. A single juvenile flipped under a sign on the forest edge.

***CROTALUS HORRIDUS* (Timber Rattlesnake)**. Dawson Co.: 16.40 km NW of Dawsonville, 2.75 km NW of the intersection of HWY 342 and HWY 52, on HWY 52 (34.542944°N, 84.220707°W). 16 August 2014. B. Hudson. GMNH 50923. A single adult found dead on road (DOR).

***FARANCIA ABACURA* (Red-bellied Mudsnake)**. Cobb Co.: Intersection of Wynford Colony SW and Wynford Drive SW, Marietta (34.922229°N, 84.637641°W). 25 May 2014. S. Cornett. GMNH 50918. A single adult found dead on road (DOR).

***HETERODON PLATIRHINOS* (Eastern Hog-nosed Snake)**. Polk Co.: 8.20 km NW of Cedartown, 0.50 km NW of the intersection of Cave Springs Road and Santa Claus Road (34.061560°N, 85.321308°W). 15 May 2005. B. Hudson. GMNH 50905. A single gravid adult female found beneath a piece of roofing tin at a private residence. Walker Co.: Ridgetop approximately 1.2 km ENE of the intersection of GA SR1 and SR136 in the city of Lafeyette (34.704136°N, 85.261835°W). 1 October 2014. A. Parnell. GMNH 50917. A single juvenile found in a pool skimmer at a private residence.

***LAMPROPELTIS GETULA* (Eastern Kingsnake)**. Hall Co.: 9.70 km NE of Gainesville, 0.75 km SE of the intersection of Reservoir Drive and Old Cornelia HWY, on Reservoir Drive (34.337463°N, 83.730129°W). 30 April 2011. B. Hudson. GMNH 50890. A single sub-adult found dead on road (DOR) next to a mesic forest.

***LAMPROPELTIS TRIANGULUM* (Eastern Milksnake)**. Habersham Co.: 12.30 km NE of Helen, 0.75 km E of Tray Mountain, (≈1265 m elev.) on SE slope (34.803276°N, 83.676911°W). 20 May 2012. B. Hudson. GMNH 50900. A single juvenile flipped under a rock on a steep forested and rocky hillside.

***NERODIA ERYTHROGASTER* (Plain-bellied Watersnake)**. Murray Co.: 1.2 km ESE of the intersection of GA SR225 and Oak Hill Street, Chatsworth (34.662992°N, 84.813758°W). 20 September 2014. T. Lewis. GMNH 50919. A single adult found in a house foundation in a wooded area.

***PITUOPHIS M. MELANOLEUCUS* (Northern Pinesnake)**. Floyd Co.: 8.45 km ESE of Rome, 0.4 km W of the intersection of Sproull Road SE and Reynolds Bend Road SE, on Shoals Ferry Road (34.238928°N, 85.075805°W). 20 May 2010. H. Brooks. GMNH 50920. A single adult found near a private residence.

***SISTRURUS MILIARIUS* (Pygmy Rattlesnake)**. Banks Co.: 6.45 km S of Alto, 1.00 km W of the intersection of Wynn Lake Road and Louden Ridge Road, just S of Louden Ridge Road (34.409320°N, 83.571247°W). 30 August 2012. B. Hudson and Z. Seymour. GMNH 50899. A single adult female found coiled and basking on top of leaves in a mixed pine-hardwood forest.

***STORERIA OCCIPITOMACULATA* (Red-bellied Snake)**. Fannin Co.: 13.20 km NW of Suches, 0.45 km SW of the intersection of Rock Creek Road and Rivers End Trail (34.741573°N, 84.151659°W). 14 June 2010. B. Hudson and T. Stratmann. Verified by Kenneth L. Krysko. FMNH 165472. A single adult found crossing a small gravel road on Blue Ridge Wildlife Management Area.

Acknowledgments.—We thank J. Jensen and the Georgia Department of Natural Resources for quickly verifying that our records remained undocumented. N. Castleberry helped tremendously by verifying and accessioning our records, as did K. Krysko and E. McGhee. We thank those in charge of Blue Ridge and Wilson Shoals Wildlife Management Areas for their continued support in our herpetological endeavors. Special thanks are given to the numerous private landowners who gave permission for us to document these records, including the Williams, White, Finlayson, Ferrier, Goodson, Chambless, Cash, Crunkleton, Rush, and Hudson families.

Significant New Records of Amphibians and Reptiles from Georgia, USA

Distributional maps found in *Amphibians and Reptiles of Georgia* (Jensen et al. 2008), along with subsequent geographical distribution notes published in *Herpetological Review*, serve as essential references for county-level occurrence data for herpetofauna in Georgia. Collectively, these resources aid biologists by helping to identify distributional gaps for which to target survey efforts. Herein we report newly documented county records for a variety of amphibian and reptile species in Georgia. All records below were verified by David Bechler (VSU), Nikole Castleberry (GMNH), David Laurencio (AUM), Lance McBrayer (GSU), and David Steen (SRSU), and datum used was WGS84. Standard English names follow Crother (2012).

CAUDATA — SALAMANDERS

***AMBYSTOMA OPACUM* (Marbled Salamander)**. Calhoun Co.: 7.8 km W Leary (31.488749°N, 84.595917°W). 18 October 2014. D. Stevenson. GMNH 50875. Lowndes Co.: Langdale Park, Valdosta (30.878524°N, 83.317114°W). 3 April 1998. J. Evans. VSU C0015. First Georgia record for the Suwannee River drainage. Murray Co.: Conasauga Natural Area (34.845116°N, 84.848180°W). 12 November 2013. N. Klaus and C. Muise. GMNH 50548.

***AMBYSTOMA TALPOIDEUM* (Mole Salamander)**. Berrien Co.: St. Hwy. 168, 3.9 km W of jct. with St. Hwy. 135 (31.177228°N, 83.125489°W). 28 February 1995. R. Moulis and G. Williamson. GSU 22356.

***DESMOGNATHUS CONANTI* (Spotted Dusky Salamander)**. Glascock Co.: Unnamed tributary of Joes Creek at St. Hwy. 102, 1.8 km of Mitchell (33.22882°N, 82.68713°W). 14 May 2014. S. Graham, C. Kelehear, J. Jensen, and B. Edelbrock. SRSU 6638.

***EURYCEA CIRRIGERA* (Southern Two-lined Salamander)**. Glascock Co.: Sphagnum seepage along Deep Creek downstream from Blankenship Pond on S side of Blankenship Mill Road (33.25627°N, 82.54572°W). 14 May 2014. S. Graham, C. Kelehear, J. Jensen, and B. Edelbrock. SRSU 6637.

***EURYCEA GUTTOLINEATA* (Three-lined Salamander)**. Clay Co.: Ravine along Ledbetter Branch, 1.6 km ESE of Ft. Gaines (31.59541°N, 85.04153°W). 14 May 2014. S. Graham and C. Kelehear. AUM AHAP-D 00839.

***HEMIDACTYLIUM SCUTATUM* (Four-toed Salamander)**. Lumpkin Co.: 8 km W Dahlonega (34.536929°N, 84.031054°W). 17 September 2009. G. Gilbert. GMNH 50512. Stephens Co.: St. Hwy. 184 at Tugaloo River (34.64407°N, 83.28468°W). 11 March 2014. A. Hall, C. Camp, M. Douglas, J. Hoffman, K. Norman, E. Rossignol, S. Thomas, and J. Whitmire. GMNH 50695.

***NOTOPHTHALMUS VIRIDESCENS* (Eastern Newt)**. Bartow Co.: 1.0 km SW jct. of Pine Valley and Pleasant Valley roads (34.329335°N, 84.875640°W). 11 March 2014. J. Jensen, T. Patrick, and M. Medley. GMNH 50758.

***PLETHODON GLUTINOSUS* (Northern Slimy Salamander)**. Cherokee Co.: S. Cherokee Lane (34.075512°N, 84.468509°W). 14 April 2014. P. Higgins. GMNH 50877.

***PLETHODON GROBMANI* (Southeastern Slimy Salamander)**. Lanier Co.: 2.1 km SW Stockton (30.932697°N, 83.021096°W). 22 October 2013. D. Stevenson. GMNH 50545.

***PSEUDOTRITON RUBER* (Red Salamander)**. Clay Co.: Ravine along Ledbetter Branch, 1.6 km ESE of Ft. Gaines (31.59541°N, 85.04153°W). 14 May 2014. S. Graham and C. Kelehear. AUM AHAP-D 00840.

***SIREN INTERMEDIA* (Lesser Siren)**. Candler Co.: Canoochee River at Stillmore Highway, 5.4 km SE Stillmore (32.426030°N, 82.161521°W). W. Vaigneur. 29 August 2014. GSU 25388.

***STEREOCHILUS MARGINATUS* (Many-lined Salamander)**. Screven Co.: Horse Creek at St. Hwy. 21, 12.5 km ESE Millen (32.793188°N, 81.815821°W). 7 April 1999. T. Foard. GSU 23869. Three large larvae found in pools of drying swamp.

ANURA — FROGS

***GASTROPHRYNE CAROLINENSIS* (Eastern Narrow-mouthed Toad)**. Clay Co.: Chorus recorded along Bluffton-Ft. Gaines Road (31.52889°N, 84.94924°W). 14 May 2014. S. Graham and C. Kelehear. AUM AHAP-C 0048.

***HYLA AVIVOCA* (Bird-voiced Treefrog)**. Clay Co.: Chorus recorded along Bagby Parkway at George T. Bagby State Park (31.66371°N, 85.05223°W). 13 May 2014. S. Graham and C. Kelehear. AUM AHAP-C 0045.

***HYLA CHRYSOSCELIS* (Cope's Gray Treefrog)**. Clay Co.: Chorus recorded along St. Hwy. 266, 2.2 km NNE of Ft. Gaines (31.62725°N, 85.03888°W). 13 May 2014. S. Graham and C. Kelehear. AUM AHAP-C 0046.

***HYLA CINEREA* (Green Treefrog)**. Chattooga Co.: Swamp off Everett Springs Road (34.528110°N, 85.116789°W). 31 May 2014. P. Higgins. GMNH 50794. Whitfield Co.: Lakeshore Park (34.750814°N, 84.975696°W). 24 June 2014. K. Esters. GMNH 50781.

***HYLA SQUIRELLA* (Squirrel Treefrog)**. Clay Co.: Chorus recorded along Bluffton-Ft. Gaines Road (31.52889°N, 84.94924°W). 14 May 2014. S. Graham and C. Kelehear. AUM AHAP-C 0047.

***LITHOBATES CAPITO* (Gopher Frog)**. Irwin Co.: 12.0 km SW Ocilla (31.52479°N, 83.347385°W). 31 May 2014. B. Schlimm and M. Moore. GMNH 50765.

***LITHOBATES CATESBEIANUS* (American Bullfrog)**. Brantley Co.: St. Hwy. 82, 0.1 km N CR 68, E 0.2 km (31.20126°N, 82.00816°W). 9 March 2012. R. Horan III. GMNH 50279, 50280.

***LITHOBATES HECKSCHERI* (River Frog)**: Cook Co.: Reed Bingham State Park (31.176612°N, 83.538607°W). 7 December 2013. K. Stohlgren. GMNH 50670.

***OSTEOPILUS SEPTENTRIONALIS* (Cuban Treefrog)**. Camden Co.: 112 Azalea Court, Kingsland (30.791284°N, 81.651727°W). 13 September 2013. E. Dealto. GMNH 50511. Multiple individuals of this invasive exotic were discovered at this site suggesting a likely established local population, the first for the state.

***PSEUDACRIS CRUCIFER* (Spring Peeper)**. Brantley Co.: Jct. St. Hwy. 121 and Bay Road (31.16794°N, 82.13242°W). 9 March 2012. R. Horan III. GMNH 50295, 50296.

***SCAPHIOPUS HOLBROOKII* (Eastern Spadefoot)**. Clay CO.: AOR Bluffton-Ft Gaines Road, 200 m NW of Huckleberry Creek (31.55408°N, 84.97495°W). 14 May 2014. S. Graham and C. Kelehear. AUM AHAP-D 00838.

TESTUDINES — TURTLES

***APALONE FEROX* (Florida Softshell)**. Laurens Co.: Private residence on NeSmith Road, Dexter (32.396984°N, 83.082839°W). 6 May 2014. T. Thomas. GMNH 50757.

***APALONE SPINIFERA* (Spiny Softshell)**. Calhoun Co.: 1.9 km NNW Arlington (31.455767°N, 84.732517°W). 2 July 2004. C. Craig. VSU TE0022. Screven Co.: 15.8 km NE Sylvania (32.810300°N, 81.484418°W). 22 September 2013. J. Oguni and B. Boone. GMNH 50515. Treutlen Co.: 13.3 km SW Soperton. Oconee River at St. Hwy 46 (32.295950°N, 82.697551°W). D. Stevenson. 24 August 2014. GMNH 50788.

***CHELYDRA SERPENTINA* (Snapping Turtle)**. Brantley Co.: St. Hwy. 82, 0.1 km N CR 68, E 0.2 km (31.20126°N, 82.00816°W). 27 August 2011. R. Horan III. GMNH 50221. Clay Co.: U.S. Hwy. 27 at Little Pachitla Creek (31.61711°N, 84.82995°W). 12 July 2014. S. Graham. AUM AHAP-D 00845. Echols Co.: Statenville (30.701985°N, 83.027950°W). 6 July 2013. D. Stevenson. GMNH 50533.

***DEIROCHELYS RETICULARIA* (Chicken Turtle)**. Candler Co.: St. Hwy. 46 at the Canoochee River floodplain, 6.4 km WSW Metter (32.384371°N, 82.126027°W). 5 July 2014. W. Vaigneur. GMNH 50789.

***GRAPTEMYS GEOGRAPHICA* (Northern Map Turtle)**. Walker Co.: Hog Jowl Creek adjacent to Hog Jowl Road 2.8 km S of jct. with Captain Wood Road (34.683891°N, 85.408315°W). 10 April 2014. J. Jensen and C. Camp. GMNH 50697.

***KINOSTERNON BAURII* (Striped Mud Turtle)**: Wheeler Co.: Little Ocmulgee Lake, Little Ocmulgee State Park (32.088084°N, 82.893400°W). June 2013. Photo of captive maintained by State Park staff. GMNH 50666.

***KINOSTERNON SUBRUBRUM* (Eastern Mud Turtle)**. Atkinson Co.: 11.1 km S Willacoochee (31.240493°N, 83.039860°W). 19 March 2014. K. Stohlgren. GMNH 50754.

***PSEUDEMYS CONCINNA* (River Cooter)**. Rabun Co.: Lake Burton, Timpson Cove; 10.5 km WSW Clayton (34.878203°N, 83.400953°W). 14 July 2014. C. Jenkins. GMNH50786. Toombs Co.: Old River Road 5.0 km W of U.S. Hwy 1 (31.976058°N, 82.406225°W). 6 June 2014. M. Moore. GMNH 50783.

***PSEUDEMYS FLORIDANA* (Coastal Plain Cooter)**. Brooks Co.: 16.6 km SE Quitman (30.676041°N, 83.441144°W). 26 June 2014. D. Stevenson. GMNH 50772.

***STERNOTHERUS MINOR* (Loggerhead Musk Turtle)**. Candler Co.: Canoochee River at Stillmore Hwy., 5.4 km SE Stillmore

(32.426030°N, 82.161521°W). W. Vaigneur. 25 May 2014. GMNH 50792. Echols Co.: Statenville (30.704383°N, 83.032489°W). 1998. Valdosta State University Ichthyology Class. VSU TE0057. Wheeler Co.: Little Ocmulgee State Park, Little Ocmulgee Lake (32.088084°N, 82.893400°W). June 2013. Photo of captive maintained by State Park staff. GMNH 50667.

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle)**. Atkinson Co.: 16.4 km SW Pearson (31.192514°N, 82.973532°W). 10 August 2014. D. Stevenson and F. Snow. GSU 25355. Wayne Co.: Penholloway Creek at State Hwy 301, 12.1 km SSW Jesup (31.500825°N, 81.913615°W). 11 September 2014. D. Stevenson. GSU 25367.

***TERRAPENE CAROLINA* (Eastern Box Turtle)**. Candler Co.: Hwy. 46 on the W side of Metter (32.396490°N, 82.077344°W). 12 May 2014. W. Vaigneur. GMNH 50791.

***TRACHEMYS SCRIPTA* (Pond Slider)**. Brantley Co.: St. Hwy. 82, 0.2 km E of Brantley County High School (31.19640°N, 82.03311°W). 10 March 2012. R. Horan III. GMNH 50294. Randolph Co.: CR 3 (31.82813°N, 84.64143°W). 03 May 2014. S. Graham, C. Kelehear, C. Guyer, B. Batistella, and S. Hermann. AUM AHAP-D 00846.

SQUAMATA — LIZARDS

***ANOLIS CAROLINENSIS* (Green Anole)**. Irwin Co.: 13.6 km SW Ocilla (31.521994°N, 83.367475°W). 31 May 2014. B. Schlimm and M. Moore. GMNH 50764.

***ANOLIS SAGREI* (Brown Anole)**. Thomas Co.: In front of The Plaza Restaurant on South Broad Street, Thomasville (30.835751°N, 83.978407°W). 20 October 2014. J. Turner. GMNH 50881. Non-native species.

***ASPIDOSCELIS SEXLINEATA* (Six-Lined Racerunner)**. Colquitt Co.: 4.5 km SE Doerun (31.2964356°N, 83.8779249°W). 14 April 2014. K. Stohlgren. GMNH 50753. Tift Co.: Private tract south of Chula-Brookfield Road (31.5389294°N, 83.4648996°W). 27 June 2013. B. Thesing. GMNH 50768.

***HEMIDACTYLUS TURCICUS* (Mediterranean House Gecko)**. Calhoun Co: Chickasawatchee Wildlife Management Area campground, 6.5 km ENE Leary (31.498384°N, 84.447135°W). Found in firewood pile. 19 November 2013. K. Stohlgren. GMNH 50671. Terrell Co.: 341 Stonewall St. SE, Dawson (31.770951°N, 84.445517°W). 28 September 2013. N. McGhee. GMNH 50546.

***OPHISAURUS ATTENUATUS* (Slender Glass Lizard)**. Telfair Co.: Orianne Society Indigo Snake Preserve (31.857214°N, 82.830899°W). 16 June 2014. B. Schlimm. GMNH 50780.

***PLESTIODON ANTHRACINUS* (Coal Skink)**. Taylor Co.: Fall Line Sandhills Wildlife Management Area, West Tract (32.560230°N, 84.399777°W). 21 April 2014. B. Morrison. GMNH 50759.

***PLESTIODON FASCIATUS* (Common Five-lined Skink)**. Jasper Co.: Private residence on State Hwy. 16 E, Monticello (33.298980°N, 83.662902°W). 22 August 2014. J. Jensen. GMNH50886.

***PLESTIODON INEXPECTATUS* (Southeastern Five-lined Skink)**. Talbot Co.: Camping area at Big Lazer Creek WMA at jct. of Bunkham Road and River Road (32.78691°N, 84.42266°W). 05 June 2014. S. Graham, C. Kelehear, B. Batistella. AUM AHAP-D 00841.

***SCELOPORUS UNDULATUS* (Eastern Fence Lizard)**. Echols Co.: Woodpecker Route at Perch Creek (30.635230°N, 82.660863°W). 29 March 2014. J. Oguni, M. King, A. King. GMNH 50892.

***SCINCELLA LATERALIS* (Little Brown Skink)**. Irwin Co.: 13.6 km SW Ocilla (31.521994°N, 83.367475°W). 31 May 2014. B. Schlimm and M. Moore. GMNH 50766.

SQUAMATA — SNAKES

***AGKISTRODON CONTORTRIX* (Copperhead)**. Chattooga Co.: Everett Springs Road (34.579204°N, 85.09064°W). 12 July 2014. P. Higgins. GMNH 50895. Taylor Co.: Wesley Church Road 0.9 km from jct. with Jinks Road (32.604767°N, 84.357383°W). 7 May 2014. R. Herrington. GMNH 50782.

***AGKISTRODON PISCIVORUS* (Cottonmouth)**. Johnson Co.: 11.4 km NW Wrightsville (32.729084°N, 82.719835°W). 15 July 2014. J. Sumner. GMNH 50790.

***CARPHOPHIS AMOENUS* (Common Wormsnake)**. Lamar Co.: St. Hwy. 18 W, Barnesville (33.051689°N, 84.186047°W). 13 April 2014. C. Muise and D. Love. GMNH 50756.

***CEMOPHORA COCCINEA* (Scarletsnake)**. Berrien Co.: 12.5 km SSW Willacoochee (31.232022°N, 83.076511°W). 16 June 2013. Kelsie Kincaid. GMNH 50755. Brantley Co.: St. Hwy. 82, 0.1 km N CR 68, E 0.2 km (31.20126°N, 82.00816°W). 20 August 2011. R. Horan III. GMNH 50167. Jenkins Co.: Doyle Road (CR 6) 0.16 km SW of Beaverdam Creek (32.951425°N, 81.858218°W). 25 May 1997. D. Holland and R. Legere. GSU 24028. Laurens Co.: Riverbend Wildlife Management Area (32.465540°N, 82.815255°W). 9 June 2014. D. Larson. GMNH 50784. Lowndes Co.: 14.6 km NW Valdosta (30.875093°N, 83.422990°W). 5 July 1998. D. Bechler. VSU SE0125. Tattnall Co.: 5.7 km SSW Glennville (31.890900°N, 81.956200°W). 27 May 2014. D. Stevenson. GSU 25352. Wheeler Co.: 13.6 km SE Alamo (32.043645°N, 82.700007°W). 12 May 2014. B. Schlimm. GMNH 50767.

***COLUBER FLAGELLUM* (Coachwhip)**. Lowndes Co.: 898 Long Pond Road, Lake Park (30.692959°N, 83.184372°W). 26 March 2001. P. Futch. VSU SE0054. Wayne Co.: 1.0 km NNE Mount Pleasant (31.442290°N, 81.676451°W). 7 November 2013. D. Stevenson. GMNH 50649.

***CROTALUS HORRIDUS* (Timber Rattlesnake)**. Chattooga Co.: Everett Springs Road (34.528490°N, 85.116822°W). 25 June 2012. P. Higgins. GMNH 50795.

***DIADOPHIS PUNCTATUS* (Ring-necked Snake)**. Clay Co.: CR 9 at Kolomoki Creek (31.49881°N 84.97361°W). 14 May 2014. S. Graham and C. Kelehear. AUM AHAP-D 00842.

New Distribution Records of Amphibians and Reptiles in West-Central Georgia, USA

The geographic region of Georgia known as the Piedmont Plateau has a diverse herpetofauna. Specimens of the following species were collected to increase the knowledge and accuracy of information with regard to their ranges and habitats. Coordinates are based on datum WGS 84. Specimens were collected under Georgia Department of Natural Resources Scientific Collections Permits (29-WJH-13-126) CN:25018 and (29-WJH-14-159) CN: 25018, and Gordon State College Institutional Animal Care and Use Committee Protocols IACUC-002-2014 and IACUC-008-2014. All of the specimens described herein are fluid-preserved vouchers housed in the Gordon State College Collection of Vertebrates (GSC). Standard English names follow Crother (2012).

CAUDATA — SALAMANDERS

***AMBYSTOMA OPACUM* (Marbled Salamander).** Butts Co.: Halls Bridge Road in Stark (33.346579°N, 83.905007°W). 11 April 2013. J. Strickland. Verified by Michael J. Bender. GSC 050. This species has been documented in five (Henry, Jasper, Monroe, Newton, and Spalding) of the six adjoining counties (Jensen et al. 2008). Salamander was found alive beneath a rock in a flower bed.

***DESMOGNATHUS CONANTI* (Spotted Dusky Salamander).** Butts Co.: Halls Bridge Road in Stark (33.346324°N, 83.904854°W). 17 April 2013. J. Strickland. Verified by John B. Jensen. GSC 052. This species has been documented in four (Jasper, Lamar, Monroe, and Newton) of the six adjoining counties (Jensen et al. 2008). Salamander was found alive underneath a rock in Caney Creek in the afternoon. Henry Co.: Leguin Mill Road in Ola (33.379741°N, 84.040813°W). 30 April 2014. J. Strickland. Verified by John B. Jensen. GSC 069. This species has been documented in five (Butts, Clayton, DeKalb, Newton, and Rockdale) of the six adjoining counties (Jensen et al. 2008; this paper). Salamander was found alive underneath leaf litter on a sandbar.

***EURYCEA CHAMBERLAINI* (Chamberlain's Dwarf Salamander).** Pike Co.: 1096 Day Road in Meansville (32.979112°N, 84.365559°W). 26 March 2014. J. Strickland. Verified by John B. Jensen. GSC 062. This species has been documented in two (Lamar and Meriwether) of the four adjoining counties (Jensen et al. 2008, West and Hartman 2014). Salamander was found underneath a rotting log that was partially submerged in a marsh.

***HEMIDACTYLIUM SCUTATUM* (Four-toed Salamander).** Butts Co.: Halls Bridge Road in Stark (33.346667°N, 83.904451°W). 8 March 2014. J. Strickland. Verified by Michael J. Bender. GSC 061. This species has been documented in two (Jasper and Newton) of the six adjoining counties (Jensen et al. 2008). Salamander was found alive inside of a rotting log that was partially submerged in a marsh.

***PLETHODON GLUTINOSUS* (Northern Slimy Salamander).** Butts Co.: Halls Bridge Road in Stark (33.346516°N, 83.904718°W). 18 April 2013. J. Strickland. Verified by Michael J. Bender. GSC 054. This species has been documented in four (Henry, Jasper, Lamar, and Monroe) of the six adjoining counties (Jensen et al. 2008; Jensen et al. 2011). Salamander was found alive underneath a rotting log.

***PSEUDOTRITON RUBER* (Red Salamander).** Butts Co.: Halls Bridge Road in Stark (33.346662°N, 83.904455°W). 3 June 2013. J. Strickland. Verified by John B. Jensen. GSC 060. This species has been documented in 4 (Jasper, Lamar, Monroe, and Newton) of the six adjoining counties (Jensen et al. 2008). Salamander was found alive underneath a rotting log that was partially submerged in Caney Creek.

ANURA — FROGS

***GASTROPHRYNE CAROLINENSIS* (Eastern Narrow-mouthed Toad).** Butts Co.: Halls Bridge Road in Stark (33.347060°N, 83.904916°W). 5 August 2014. J. Strickland. Verified by Michael J. Bender. GSC 071. This species has been documented in four (Bibb, Henry, Jasper, and Newton) of the six adjoining counties (Jensen et al. 2008). Frog was found alive underneath a foam mat.

***HYLA CINEREA* (Green Treefrog).** Butts Co.: Halls Bridge Road in Stark (33.346783°N, 83.904555°W). 25 April 2014. J. Strickland. Verified by Michael J. Bender. GSC 068. This species has been documented in six (Henry, Jasper, Lamar, Monroe, Newton, and Spalding) of the six adjoining counties (Jensen et al. 2008). Frog was found alive on a tree limb overhanging Caney Creek.

***HYLA GRATIOSA* (Barking Treefrog).** Butts Co.: Halls Bridge Road in Stark (33.346780°N, 83.904551°W). 2 June 2015. J. Strickland. Verified by John B. Jensen. GSC 072. This species has been

documented in three (Jasper, Lamar, and Monroe) of the six adjoining counties (Jensen et al. 2008). Frog was found alive crossing a private drive during a thunderstorm.

***LITHOBATES SPHENOCEPHALUS* (Southern Leopard Frog)**. Pike Co.: 1096 Day Road in Meansville (32.979112°N, 84.365559°W). 26 March 2014. J. Strickland. Verified by Michael J. Bender. GSC 067. This species has been documented in three (Lamar, Meriwether, and Spalding) of the four adjoining counties (Jensen et al. 2008; Jensen et al. 2011). Frog was found alive by a rock in a small stream.

***PSEUDACRIS FERIARUM* (Upland Chorus Frog)**. Butts Co.: Halls Bridge Road in Stark (33.346788°N, 83.904557°W). 21 May 2013. J. Strickland. Verified by John B. Jensen. GSC 056. This species has been documented in three (Jasper, Monroe, and Newton) of the six adjoining counties (Jensen et al. 2008). Frog was found alive atop a rotting log.

SQUAMATA — LIZARDS

***PLESTIODON FASCIATUS* (Common Five-lined Skink)**. Butts Co.: Halls Bridge Road in Stark (33.346519°N, 83.905592°W). 1 June 2013. J. Strickland. Verified by Michael J. Bender. GSC 058. This species has been documented in three (Henry, Monroe, and Newton) of the six adjoining counties (Jensen et al. 2008). Skink was found alive atop a rock.

***SCINCELLA LATERALIS* (Little Brown Skink)**. Butts Co.: Halls Bridge Road in Stark (33.346698°N, 83.905399°W). 1 June 2013. J. Strickland. Verified by Michael J. Bender. GSC 059. This species has been documented in five (Newton, Jasper, Henry, Lamar, and Monroe) of the six adjoining counties (Jensen et al. 2008; Jensen et al. 2011). Skink was found alive amongst leaf litter.

SQUAMATA — SNAKES

***AGKISTRODON CONTORTRIX* (Copperhead)**. Butts Co.: Halls Bridge Road in Stark (33.343200°N, 83.902655°W). 28 April 2013. J. Strickland. Verified by Michael J. Bender. GSC 051. This species has been documented in four (Jasper, Newton, Monroe, and Spalding) of the six adjoining counties (Jensen et al. 2008). Snake was found alive underneath a piece of tin roofing material.

***CEMOPHORA COCCINEA* (Scarletsnake)**. Butts Co.: Halls Bridge Road in Stark (33.346994°N, 83.905436°W). 26 June 2013. J. Strickland. Verified by Michael J. Bender. GSC 057. This species has been documented in two (Lamar and Monroe) of the six adjoining counties (Jensen et al. 2008; Jensen et al. 2011). Snake was found alive underneath a rotting log.

***DIADOPHIS PUNCTATUS* (Ring-necked Snake)**. Butts Co.: Halls Bridge Road in Stark (33.346516°N, 83.904718°W). 16 May 2013. J. Strickland. Verified by Michael J. Bender. GSC 055. This species has been documented in four (Henry, Jasper, Monroe, and Newton) of the six adjoining counties (Jensen et al. 2008). Snake was found alive amongst leaf litter.

***VIRGINIA VALERIAE* (Smooth Earthsnake)**. Butts Co.: Halls Bridge Road in Stark (33.346660°N, 83.904450°W). 8 April 2014. J. Strickland. Verified by Michael J. Bender. GSC 063. This species has been documented in three (Jasper, Henry, and Monroe) of the six adjoining counties (Jensen et al. 2008). Snake was found alive underneath a piece of plywood.

Acknowledgments.—We thank J. Jensen for reviewing a draft of the manuscript, verifying the identification of some of our specimens, and assisting us in verifying county records.

New County Records of Reptiles and Amphibians from State-Managed Properties in Illinois

The publication of *The Amphibians and Reptiles of Illinois* (Phillips et al. 1999) provided a widely available record of the known county-level distributions of herpetofauna in Illinois. Since its publication, multiple articles documenting new county records from the state have been published in *Herpetological Review* (e.g., Petzing et al. 2000, 2002, and 2007; Foster and Mullin 2007).

As part of a study examining the ecological integrity of seasonal wetlands on state-managed properties in Illinois, we repeatedly sampled 240 wetlands over three years for the presence of amphibians and reptiles. The study resulted in 17 new Illinois county records collected from 2010–2012 (Kessler et al 2013). Herein we report 19 specimens collected in 2013 and 2014 that represent new county records in the state of Illinois as well as two vouchered specimens that were previously known only from photographs. All vouchered specimens listed are housed in the Illinois Natural History Survey (INHS) amphibian and reptile collection.

County records were confirmed using the Illinois Herpetological Database at INHS, which contains records of Illinois amphibians and reptiles from 30 museum collections as well as a collection of photographs of unvouchered specimens and observations from herpetologists and state biologists, and by examining volumes of *Herpetological Review* published since Phillips et al. (1999). Coordinates are presented in decimal degrees using map datum WGS 84. Scientific and common names follow Crother (2012).

CAUDATA — SALAMANDERS

***AMBYSTOMA TEXANUM* (Small-mouthed Salamander).** Adams Co.: Siloam Springs State Park, 16 km E of Liberty (39.88455°N, 90.92078°W). 23 October 2013. A. R. Kuhns and C. A. Phillips. Verified by D. B. Wylie. INHS 23643. One of four young-of-year found under log in dry vernal wetland. Brown Co.: Siloam Springs State Park- Buckhorn Unit; 11.8 km SW of Mount Sterling (39.90165°N, 90.84560°W). 19 March 2014. E. J. Kessler and C. E. Cook. Verified by C. A. Phillips. INHS 23897. Captured in a minnow trap in an ephemeral wetland.

***AMBYSTOMA TIGRINUM* (Eastern Tiger Salamander).** Massac Co.: Sielbeck Forest State Natural Area; 8.1 km ENE of Joppa (37.22499°N, 88.75672°W). 7 February 2013. A. R. Kuhns, C. M. Rhoden, E. J. Kessler, and E. M. Wright. Verified by D. B. Wylie. INHS 22991. Captured in minnow trap in semi-permanent wetland.

***NOTOPTHALMUS VIRIDESCENS* (Eastern Newt).** Massac Co.: Fort Massac State Park; 3.0 km E of Metropolis (37.16076°N, 88.69995°W). 22 May 2013. A. R. Kuhns, J. D. Folkerts, and A. K. Keigher. Verified by C. A. Phillips. INHS 23338. Captured in minnow trap in wetland. Randolph Co.: Randolph County State Recreation Area; 7.0 km N of Chester (37.97963°N, 89.80649°W). 12 March 2014. A. R. Kuhns, A. K. Keigher, and S. J. Gerstman. Verified by C. A. Phillips. INHS 23872. Captured in minnow trap placed in pond with submergent vegetation.

***SIREN INTERMEDIA* (Lesser Siren).** Jefferson Co.: Wayne Fitzgerrell State Recreation Area; 7.1 km SE of Waltonville (38.16762°N, 88.97731°W). 25 February 2014. A. R. Kuhns, E. J. Kessler, J. A. Crawford, and C. E. Cook. Verified by C. A. Phillips. INHS 23841. Adult found dead under ice in permanent pond. Saline Co.: Saline County Conservation Area; 5.1 km SW of Equality (37.69828°N, 88.37889°W). 19 February 2014. A. R. Kuhns, J. P. Ross, A. K. Keigher, and C. A. Phillips. Verified by D. B. Wylie. INHS 23844. Adult caught in minnow trap in floodplain wetland.

ANURA — FROGS

***ANAXYRUS AMERICANUS* (American Toad).** Jefferson Co.: Rend Lake State Fish and Wildlife Area; 2.3 km S of Bonnie (38.18642°N, 88.91930°W). 11 April 2014. E. J. Kessler and C. E. Cook. Verified by C. A. Phillips. INHS 23953.Captured in ephemeral wetland in woodlot near wildlife food plot. Massac Co.: Mermet Lake State Fish and Wildlife Area; 9.9 km E of Karnak (37.27881°N, 88.86499°W). 18 April 2013. E. J. Kessler, C. M. Rhoden, and C. A. Phillips. Verified by D. B. Wylie. INHS 23267. Adult caught in a pitfall trap near an ephemeral wetland.

***PSEUDACRIS CRUCIFER* (Spring Peeper).** Adams Co.: Siloam Springs State Park; 16 km E of Liberty (39.89251°N, 90.92080°W). 20 March 2014. E. J. Kessler and C. E. Cook. Verified by C. A. Phillips. INHS 23915. Chorusing in shallow wooded wetland.

***LITHOBATES CLAMITANS* (Green Frog)**. Brown Co.: Siloam Springs State Park; 16.5 km E of Liberty (39.88979°N, 90.91503°W). 24 October 2013. A. R. Kuhns and C. A. Phillips. Verified by D. B. Wylie. INHS 23639. Juvenile captured from small intermittent stream.

***LITHOBATES PIPIENS* (Northern Leopard Frog)**. Peoria Co.: Jubilee College State Park; 7.3 km ESE of Brimfield (40.81179°N, 89.80737°W). 10 April 2013. E. J. Kessler, C. M. Rhoden, and J. D. Folkerts. Verified by C. A. Phillips. INHS 23254. Large chorus from created wetland.

TESTUDINES — TURTLES

***CHELYDRA SERPENTINA* (Snapping Turtle)**. Franklin Co.: Wayne Fitzgerrell State Recreation Area; 4.4 km WNW of Whittington (38.10999°N, 88.94483°W). 7 June 2013. E. J. Kessler, C. M. Rhoden, and A. R. Kuhns. Verified by D. B. Wylie. INHS 23329. Juvenile caught in minnow trap in ephemeral wetland. Previously only known in the county from photo voucher.

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle)**. Johnson Co.: Heron Pond-Wildcat Bluff Nature Preserve; 5.3 km SSW of Vienna (38.37358°N, 88.92725°W). 17 April 2013. C. A. Phillips, E. J. Kessler, and C. M. Rhoden. Verified by D. B. Wylie. INHS 23302. Carapace and plastron found at edge of cypress swamp. Juvenile (INHS 23380) captured following day at Ferne Clyffe State Park (Johnson Co.). Previously only known in the county from photo voucher.

***TRACHEMYS SCRIPTA* (Pond Slider)**. Franklin Co.: Wayne Fitzgerrell State Recreation Area; 4.4 km WNW of Whittington (38.10999°N, 88.94483°W). 7 June 2013. E. J. Kessler, C. M. Rhoden, and A. R. Kuhns. Verified by D. B. Wylie. INHS 23330. Juvenile caught in minnow trap in ephemeral wetland.

SQUAMATA — LIZARDS

***EUMECES FASCIATUS* (Five-lined Skink)**. Franklin Co.: Wayne Fitzgerrell State Recreation Area; 3.6 km WNW of Whittington (38.09579°N, 88.94275°W). 4 June 2013. E. J. Kessler and C. M. Rhoden. Verified by D. B. Wylie. INHS 23381. Adult found under log near ephemeral wetland.

***EUMECES LATICEPS* (Broad-headed Skink)**. Massac Co.: Mermet Lake State Fish and Wildlife Area; 2.8 km S of Goreville (37.52967°N, 88.97050°W). 21 May 2013. E. J. Kessler and C. M. Rhoden. Verified by D. B. Wylie. INHS 23336. One of three individuals captured at the site in the same week.

***SCINCELLA LATERALIS* (Little Brown Skink)**. Cass Co.: Jim Edgar Panther Creek State Fish and Wildlife Area; 4.2 km SE of Chandlerville (40.01703°N, 90.12729°W). 3 April 2013. E. J. Kessler and C. M. Rhoden. Verified by D. B. Wylie. INHS 23383. Adult captured in pitfall trap along drift fence array.

SQUAMATA — SNAKES

***STORERIA DEKAYI* (Dekay's Brownsnake)**. Jefferson Co.: Rend Lake State Fish and Wildlife Area; 6.4 km WNW of Ina (38.16559°N, 88.97446°W). 20 June 2014. C. E. Cook, C. E. Butkus, and S. Hernandez. Verified by D. B. Wylie. INHS 24008. Adult captured near ephemeral wetland. Massac Co.: Fort Massac State Park; 2.4 km NW of Brookport (37.13604°N, 88.65221°W). 17 April 2013. A. K. Keigher and J. D. Folkerts. Verified by D. B. Wylie. INHS 23399. Adult captured in funnel trap along drift fence array.

***STORERIA OCCIPITOMACULATA* (Red-bellied Snake)**. Saline Co.: Saline County State Fish and Wildlife Area; 5.5 km SW of Equality (37.69284°N, 88.37859°W). 2 April 2014. A. K. Keigher, S. J. Gerstman, and A. R. Kuhns. Verified by D. B. Wylie. INHS 23928. Adult captured in funnel trap along fence array.

Acknowledgments.—We thank the Illinois Department of Natural Resources (IDNR) land managers who granted us permission to conduct research in their parks and aided us in accessing wetlands on their properties. Thanks also go to the Illinois Natural History Survey Museum Collections Manager D. Wylie for cataloging and verifying specimens. Field work was supported by United States Environmental Protection Agency Region 5 Wetlands Program Development Grant CD-00E00963, and an IDNR Wildlife Preservation Fund Grant 14-033W. Fieldwork was conducted under permits from the Illinois Department of Natural Resources to work on state managed properties, collecting permits to C. A. Phillips and A. R. Kuhns and, when applicable, IDNR Endangered and Threatened Species Permit, 05-11S. Field sampling was conducted under University of Illinois Institutional Animal Care and Use Committee Protocol 11203.

New Distributional Records for the Herpetofauna of Texas

From a historical perspective, the state of Texas has been one of the most herpetologically diverse and traditionally sampled areas of the country. However, primarily due to collecting bias, several areas of Texas remain overlooked, particularly areas that lie outside of the Trans-Pecos region, and several species of herpetofauna tend to be largely unnoticed as well. Here we report on new county records that serve as either range extensions or that function as the "filling in" of distributional gaps for numerous species of amphibians and reptiles in several counties of Texas.

Although the majority of these records have been recorded within the past several years, many of these observations are of specimens that were discovered, journaled, and photographed without recognition of their significance. Therefore, many of the observations reported herein go back to the latter part of last century.

From 1986 to present, fieldwork has been conducted in the following 18 counties: Borden, Crane, Crockett, Ector, Gaines, Garza, Glasscock, Hale, Hockley, Irion, Midland, Runnels, Schleicher, Scurry, Sterling, Sutton, Taylor, and Upton. Voucher specimens or photographs were deposited into the Biodiversity Collections (formerly the Texas Natural History Collections) at The University of Texas at Austin (TNHC) and all vouchers were verified by Travis J. LaDuc. Coordinates and elevations of observation sites were taken with a GPS device using map datum WGS 84.

A total of 66 records comprised of 47 species of amphibians and reptiles are reported for the first time in the counties listed above. The new county records are listed below. Standard English names follow Crother (2012).

CAUDATA — SALAMANDERS

***AMBYSTOMA MAVORTIUM* (Western Tiger Salamander).** Borden Co.: Gail, 0.48 air mi N on RM 669 (32.77738°N, 101.44652°W), 2529 ft elev. 20 June 2009. T. M. Dimler. TNHC 89529. Fills distributional gap.

ANURA— FROGS

***ANAXYRUS COGNATUS* (Great Plains Toad).** Scurry Co.: Snyder, 7.56 air mi WSW on private ranch (32.69028°N, 101.04617°W), 2292 ft elev. May 1991. M. S. Price. TNHC 92932, photo voucher. Extends distributional record.

***ANAXYRUS DEBILIS DEBILIS* (Eastern Chihuahuan Green Toad).** Scurry Co.: Snyder, 7.56 air mi WSW on private ranch (32.69028°N, 101.04617°W), 2292 ft elev. May 1991. M. S. Price. TNHC 92933, photo voucher. Fills distributional gap.

TRAVIS M. DIMLER
West Texas Herpetological Society, P.O. Box 411,
Gail, Texas 79738, USA; e-mail: travisdimler@sbcglobal.net

***ANAXYRUS PUNCTATUS* (Red-spotted Toad).** Scurry Co.: Snyder, 7.56 air mi WSW on private ranch (32.69028°N, 101.04617°W), 2292 ft elev. May 1991. M. S. Price. TNHC 92934, photo voucher. Fills distributional gap.

***ANAXYRUS SPECIOSUS* (Texas Toad).** Borden Co.: Gail, 9.79 air mi NNE on private ranch (32.91113°N, 101.42322°W), 2534 ft elev. 9 May 2009. T. M. Dimler. TNHC 84916. Fills distributional gap.

***ELEUTHERODACTYLUS MARNOCKII* (Cliff Chirping Frog).** Crockett Co.: Ozona, 32.37 air mi SW on RM 2083 (30.32592°N, 101.52662°W). 1915 ft elev. 14 June 2015. M. S. Price, N. M. Price, and S. G. Price. TNHC 95430, photo voucher. Fills distributional gap.

***GASTROPHRYNE OLIVACEA* (Western Narrow-mouthed Toad).** Borden Co.: Gail, 5.28 air mi W on private ranch (32.75718°N, 101.53513°W), 2603 ft elev. 12 October 2012. T. M. Dimler. TNHC 89542. Fills distributional gap. Midland Co.: Midland, 3.41 air mi SW on the premises of the I-20 Wildlife Preserve (31.96345°N, 102.12018°W), 2803 ft elev. 1 June 2015. M. S. Price N. R. Price, and K. Conder. TNHC 95431, photo voucher. Fills distributional gap. Scurry Co.: Snyder, 2.50 air mi SE on private residence (32.69872°N, 100.88120°W), 2355 ft elev. June 1994. M. S. Price. TNHC 92925, photo voucher. Fills distributional gap. Sterling Co.: Sterling City, 16.91 air mi SSE on RM 2034 (31.59654°N, 100.92406°W), 2397 ft elev. 20 April 2012. M. S. Price and N. M. Price. TNHC 89541. Fills distributional gap.

***LITHOBATES CATESBEIANUS* (American Bullfrog).** Midland Co.: Midland, 3.43 air mi SW on the premises of the I-20 Wildlife Preserve (31.96413°N, 102.12131°W), 2812 ft elev. 24 June 2014. M. S. Price and T. M. Dimler. TNHC 95432, photo voucher. Fills distributional gap.

***PSEUDACRIS CLARKII* (Spotted Chorus Frog).** Scurry Co.: Snyder, 13.62 air mi ENE on RM 1614 (32.73937°N, 100.68519°W), 2181 ft elev. August 1992. M. S. Price. TNHC 92922, photo voucher. Fills distributional gap.

***SCAPHIOPUS COUCHII* (Couch's Spadefoot).** Borden Co.: Gail, 13.2 air mi S on Willow Valley Road (32.56336°N, 101.39130°W), 2357 ft elev. 12 October 2009. T. M. Dimler. TNHC 89753. Fills distributional gap. Scurry Co.: Snyder, 7.56 air mi WSW on private ranch (32.69028°N, 101.04617°W), 2292 ft elev. May 1991. M. S. Price. TNHC 92935, photo voucher. Fills distributional gap.

TESTUDINES — TURTLES

***APALONE SPINIFERA GUADALUPENSIS* (Guadalupe Spiny Soft-shelled Turtle).** Scurry Co.: Snyder, 0.20 air mi SW along Deep Creek (32.71593°N, 100.92005°W), 2294 ft elev. May 1991. M. S. Price. TNHC 92919, photo voucher. Fills distributional gap.

***APALONE SPINIFERA GUADALUPENSIS* (Guadalupe Spiny Soft-shelled Turtle).** Sterling Co.: Sterling City, 3.33 air mi SE in North Concho River (31.80288°N, 100.94389°W), 2198 ft elev. 18 June 2015. M. S. Price. TNHC 95424. Fills distributional gap.

***GRAPTEMYS VERSA* (Texas Map Turtle)**. Sterling Co.: Sterling City, 3.33 air mi SE in North Concho River (31.80288°N, 100.94389°W), 2198 ft elev. 5 May 2010. M. S. Price. TNHC 92937, photo voucher. Extends distributional record.

***KINOSTERNON FLAVESCENS* (Yellow Mud Turtle)**. Crockett Co.: Ozona, 24.01 air mi N on SH 163 (31.04931°N, 101.16528°W), 2661 ft elev. 13 May 2009. M. S. Price. TNHC 92910, photo voucher. Fills distributional gap.

***PSEUDEMYS TEXANA* (Texas River Cooter)**. Sterling Co.: Sterling City, 3.33 air mi SE in North Concho River (31.80288°N, 100.94389°W), 2198 ft elev. 20 April 2013. M. S. Price. TNHC 95429, photo voucher. Fills distributional gap.

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle)**. Sterling Co.: Sterling City, 3.33 air mi SE in North Concho River (31.80288°N, 100.94389°W), 2198 ft elev. 5 May 2010. M. S. Price. TNHC 92946, photo voucher. Extends distributional record.

***TERREPENE ORNATA ORNATA* (Ornate Box Turtle)**. Upton Co.: McCamey, 19.30 air mi NNW on SH 329 (31.40741°N, 102.28381°W), 2610 ft elev. June 1997. M. S. Price and D. B. Wuerch. TNHC 92942, photo voucher. Fills distributional gap.

***TRACHEMYS SCRIPTA ELEGANS* (Red-eared Slider)**. Sterling Co.: Sterling City, 3.33 air mi SE in North Concho River (31.80288°N, 100.94389°W), 2198 ft elev. 5 May 2010. M. S. Price. TNHC 92938, photo voucher. Fills distributional gap.

SQUAMATA — LIZARDS

***ASPIDOSCELIS SEXLINEATA VIRIDIS* (Prairie Racerunner)**. Scurry Co.: Snyder, 0.53 air mi SW at private residence (32.71478°N, 100.92600°W), 2320 ft elev. April 1993. M. S. Price. TNHC 92920, photo voucher. Fills distributional gap.

***ASPIDOSCELIS TESSELATA* (Common Checkered Whiptail)**. Midland Co.: Midland, 3.62 air mi SW on the premises of the I-20 Wildlife Preserve (31.96178°N, 102.12337°W), 2826 ft elev. 25 April 2014. M. S. Price and B. Williams. TNHC 95422. Extends distributional record.

***HOLBROOKIA MACULATA MACULATA* (Great Plains Earless Lizard)**. Scurry Co.: Hermleigh, 4.82 SW on CR 4146 (32.57274°N, 100.79597°W), 2332 ft elev. April 1993. M. S. Price. TNHC 92930, photo voucher. Fills distributional gap.

***HEMIDACTYLUS TURCICUS* (Mediterranean House Gecko)**. Midland Co.: Midland, 3.18 air mi SW on the premises of the I-20 Wildlife Preserve (31.96607°N, 102.11764°W), 2815 ft elev. 18 April 2015. M. S. Price, N. M. Price, T. M. Dimler, and H. McMillan. TNHC 95423. Extends distributional record. Sterling Co.: Sterling City, on Dairy Queen building (31.83588°N, 100.98355°W), 2284 ft elev. 16 October 2012. M. S. Price. TNHC 89546. Extends distributional record. Sutton Co.: Sonora, Jct. of IH-10 & U.S. Hwy. 277 (30.58036°N, 100.64621°W), 2138 ft elev. 19 May 2011. M. S. Price and N. M. Price. TNHC 89547. Fills distributional gap.

***PLESTIODON OBSOLETUS* (Great Plains Skink)**. Midland Co.: Midland, 3.43 air mi SW on the premises of the I-20 Wildlife Preserve (31.96482°N, 102.12223°W), 2810 ft elev. 9 September 2010. M. S. Price and N. Knowles. TNHC 95428, photo voucher. Fills distributional gap.

SQUAMATA — SNAKES

***AGKISTRODON CONTORTRIX LATICINCTUS* (Broad-banded Copperhead)**. Runnels Co.: Paint Rock, 12.68 air mi E (31.49230°N, 99.70584°W), 1566 ft elev. May 2002. M. S. Price and R.L. Dearth. TNHC 89748. Extends distributional range.

***ARIZONA ELEGANS ELEGANS* (Kansas Glossy Snake)**. Scurry Co.: Snyder, 7.10 air mi S on Round Top Road (32.61551°N, 100.91970°W), 2267 ft elev. May 2004. M. S. Price. TNHC 92929, photo voucher. Fills distributional gap.

***COLUBER CONSTRICTOR FLAVIVENTRIS* (Eastern Yellow-bellied Racer)**. Borden Co.: Gail, 4.49 air mi WSW on private ranch (32.76017°N, 101.52193°W), 2559 ft elev. 18 July 2012. T. M. Dimler. TNHC 92906, photo voucher. Extends distributional range.

***CROTALUS LEPIDUS LEPIDUS* (Mottled Rock Rattlesnake)**. Schleicher Co.: Eldorado, 15.37 air mi SW on RM 2129 (30.74197°N, 100.81969°W), 2382 ft elev. 8 April 2009. M. S. Price and N. M. Price. TNHC 84918. Extends distributional range.

***CROTALUS VIRIDIS* (Prairie Rattlesnake)**. Scurry Co.: Hermleigh, 5.41 air mi SSW on CR 4136 (32.55796°N, 100.77467°W), 2352 ft elev. 14 October 2011. M. S. Price. TNHC 89750. Fills distributional gap.

***DIADOPHIS PUNCTATUS REGALIS* (Regal Ring-necked Snake)**. Borden Co.: Gail, 4.68 air mi WNW on private ranch (32.78703°N, 101.52444°W), 2639 ft elev. 19 October 2012. T. M. Dimler. TNHC 89745. Fills distributional gap. Scurry Co.: Hermleigh, 5.67 air mi WNW on private ranch (32.55937°N, 100.79331°W), 2356 ft elev. May 1991. M. S. Price. TNHC 92931, photo voucher. Fills distributional gap.

***DRYMARCHON MELANURUS* (Central American Indigo Snake)**. Sutton Co.: 0.70 air mi SE of IH-10 & U.S. Hwy. 277 (corner of Water & Pecan St. in Sonora) (30.56933°N, 100.64261°W), 2118 ft elev. 19 September 2009. M. S. Price and M. H. Humphrey. TNHC 84899. Extends distributional range.

***GYALOPION CANUM* (Chihuahuan Hook-nosed Snake)**. Midland Co.: Midland, 11.94 air mi SE on SCR 1160 (31.84537°N, 101.98024°W), 2691 ft elev. 24 June 2014. M. S. Price and A. Barentse. TNHC 95421 Fills distributional gap. Upton Co.: McCamey, 9.7 air mi NNE on private ranch (31.26706°N, 102.17448°W), 2819 ft elev. October 1996. M. S. Price and D. B. Wuerch. TNHC 92943, photo voucher. Extends distributional range.

***HETERODON PLATIRHINOS* (Eastern Hog-nosed Snake)**. Borden Co.: Gail, 11.89 air mi NE on private ranch (32.91631°N, 101.3366°W), 2654 ft elev. 22 September 2004. T. M. Dimler. TNHC 92907, photo voucher. Extends distributional record. Schleicher Co.: Eldorado, 9.49 air mi E on US 190 (30.87105°N, 100.44167°W), 2303 ft elev. 30 June 2010. M. S. Price and B. Vanecek. TNHC 92918, photo voucher. Extends distributional record.

***HYPSIGLENA JANI* (Chihuahuan Nightsnake)**. Midland Co.: Midland, 6.96 air mi SSW on SCR 1210 (31.89644°N, 102.08528°W),

2743 ft elev. 24 June 2014. M. S. Price and A. Barentse. Fills distributional gap. Scurry Co.: Snyder, 2.46 air mi SE on Brick Plant Road (32.69548°N, 100.88486°W), 2292 ft elev. June 1992. M. S. Price. TNHC 92924, photo voucher. Fills distributional gap. Upton Co.: Rankin, 13.54 air mi NW on SH 329 (31.33071°N, 102.12911°W), 2785 ft elev. June 1997. M. S. Price and D. B. Wuerch. TNHC 92940, photo voucher. Fills distributional gap.

***LAMPROPELTIS ALTERNA* (Gray-banded Kingsnake)**. Upton Co.: McCamey, 11.08 air mi NE on private ranch (31.28823°N, 102.17560°W), 3030 ft elev. May 1995. M. S. Price and D. B. Wuerch. TNHC 95426, photo voucher. Extends distributional range.

***LAMPROPELTIS GETULA SPLENDIDA* (Desert Kingsnake)**. Upton Co.: McCamey, 19.31 air mi NNW on SH 329 (31.40625°N, 102.29046°W), 2607 ft elev. June 1997. M. S. Price and D. B. Wuerch. TNHC 92941, photo voucher. Fills distributional gap.

***LAMPROPELTIS TRIANGULUM* (Milksnake)**. Ector Co.: Penwell, 2.78 air mi SSE on RM 1601 (31.70203°N, 102.57582°W), 2879 ft elev. May 1997. M. S. Price and M. Adcox. TNHC 92911, photo voucher. Fills distributional gap. Gaines Co.: Seminole, 19.76 air mi SW on CR 324 (32.55763°N, 102.92518°W), 3418 ft elev. August 2004. M. S. Price and M. Webb. TNHC 92912, photo voucher. New County Records of Reptiles from the Suwannee River, Florida, USA

These records were collected during a turtle study from July 2011 through December 2013 in the Suwannee River, Florida. The Suwannee River serves as the boundary between counties, and we considered a capture as a new county record (Krysko et al. 2011) only if it came from the correct side of the river. Many counties along the Suwannee River are rural, potentially explaining why many of these new records represent common species. *Trachemys scripta elegans*, which is not native to Florida, appears to be distributed throughout the entire Suwannee River in Florida and is apparently reproducing. A large female captured in Gilchrist County (UF 174471) laid an egg soon after capture. This is of concern because this non-native subspecies can intergrade with native *T. s. scripta*. We removed all captured *T. s. elegans* from the wild. Records were verified by Kenneth L. Krysko, and digital photographic vouchers were deposited in the Florida Museum of Natural History (UF). Geocoordinates are based on datum WGS 84. Standard English names follow Crother (2012).

TESTUDINES — TURTLES

***APALONE FEROX* (Florida Softshell).** Hamilton Co.: Suwannee River, near White Springs 150 m upstream from CR 136 bridge (30.326677°N, 82.760333°W). 23 March 2012. T. Thomas, K. Enge, and E. Suarez. UF 174417. Captured in a hoop net.

***CHELYDRA SERPENTINA* (Snapping Turtle).** Gilchrist Co.: Suwannee River, 50 m from Sun Spring's head (29.704621°N, 82.933554°W). 2 May 2012. T. Thomas and E. Suarez. UF 174418. Captured by hand.

***KINOSTERNON BAURII* (Striped Mud Turtle).** Madison Co.: Suwannee River, ~ 5.5 km downstream from I-10 bridge (30.327343°N, 83.211448°W). 17 October 2012. T. Thomas and E. Suarez. UF 174464. Captured by hand along bank. Suwannee Co.: boat ramp at the Spirit of the Suwannee Music Park (30.405882°N, 82.949105°W). 15 June 2012. T. Thomas and E. Suarez. UF 174465. Hand captured in a flooded ditch along dirt road.

***MACROCHELYS SUWANNIENSIS* (Suwannee Alligator Snapping Turtle).** Madison Co.: Suwannee River, ~ 8.5 km downstream from I-10 bridge (30.305378°N, 83.218073°W). 17 October 2012. T. Thomas and E. Suarez. UF 174466. Captured in a hoop net. Gilchrist Co.: Suwannee River, ~ 3.1 km upstream from CR 340 (29.81564°N, 82.931430°W). 7 April 2012. T. Thomas and E. Suarez. UF 169563. Captured in a hoop net.

NATURAL HISTORY NOTES

CAUDATA — SALAMANDERS

EURYCEA LUCIFUGA **(Cave Salamander). PREDATION.** Specific predator species have apparently not been reported for *Eurycea lucifuga* (Juterbock 2005. *In* M. J. Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 750–753. University of California Press, Berkeley, California). Hutchison (1958. Ecol. Monogr. 28:1–20) speculated that *Diadophis punctatus* (Ring-necked Snake) may be an important predator of *E. lucifuga* because he observed these snakes at the openings of salamander-rich caves. *Diadophis punctatus* is known to prey upon salamanders (e.g., Blanchard et al. 1979. J. Herpetol. 13:377–402). On 09 July 2015 we observed a Cave Salamander hanging by its head that appeared stuck in a rock crevice within the twilight zone of Screech Owl Cave on Pigeon Mountain, Walker Co., Georgia, USA (ca. 34.6650°N, 85.3635°W; WGS 84). Upon lifting the salamander we observed a *D. punctatus* grasping the head of the salamander. As part of an on-going effort to monitor salamanders using caves in northwestern Georgia (Camp and Jensen 2007. Copeia 2007:594–604; Camp et al. 2014. Can. J. Zool. 92:119–127) we have seen *D. punctatus* on several occasions within twilight zones of caves. However, it is unclear whether this species of snake actively forages for salamanders within this habitat or if the observed incident represents a rare, coincidental event.

JENSEN** (e-mail: John.Jensen@dnr.ga.gov), Georgia Department of Natural Resources, Nongame Conservation Section, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA.

NOTOPHTHALMUS VIRIDESCENS **(Eastern Newt). DIET.** We studied the diets of adult *Notophthalmus viridescens* from three lakes to evaluate whether adult newt diets differ across ponds locally or if they exhibit prey preferences. We conducted macroinvertebrate surveys and collected a total of 67 *N. viridescens* adults using dipnet surveys from three ponds in Sewanee, Franklin Co., Tennessee, USA (Pond 1: 35.2139°N, 85.9130°W; Pond 2: 35.2128°N, 85.9190°W; Pond 3: 35.2212°N, 85.9354°W; WGS 84), from October to December 2014. Prey surveys were standardized to four dips at ten locations around each lake. All prey organisms were identified to class or family using a dissecting microscope. Salamander diets were assessed by conducting a non-lethal lavage on each individual using protocols identified in Cecala et al. (2007. J. Herpetol. 41:741–745). 89.3% of adults had stomach contents. We conducted chi-square tests to determine if diets differed among ponds or were distinct from macroinvertebrate availability. We extracted 204 food items including organisms from the following groups ranked by abundance: Gastropoda (42.6%), Diplostraca (22.5%), Odonata (15.2%), Tricoptera (5.9%), Oligochaeta (5.9%), Diptera (2.5%), Coleoptera (1%), Plecoptera (0.5%), Ephemeroptera (0.5%), and Arachnida (0.5%). Adult newts consumed prey items in proportion to their availability (Pond 1, $\chi^2 = 1.64$, $p = 0.98$; Pond 2, $\chi^2 = 0.30$, $p = 0.99$; Pond 3, $\chi^2 = 0.93$, $p = 0.97$) despite availability of prey varying among ponds. Pond 2 and Pond 3 all had more human disturbance within their catchments than Pond 1 and had much higher densities of gastropods (Pond 1 = 0% Gastropoda, Pond 2 = 48% Gastropoda, and Pond 3 = 35% Gastropoda in prey item sampling). Because of variation in prey availability among ponds, newts also demonstrated diet variability between Pond 1 and Pond 3 ($\chi^2 = 20.30$, $p = 0.005$) but not between any other pond pairing (Pond 1 and 2, $\chi^2 = 13.03$, $p = 0.16$; Pond 2 and 3, $\chi^2 = 0.16$, $p = 0.99$). In conclusion, *N. viridescens* appears to consume prey in proportion to their availability despite pond heterogeneity in prey availability.

MARGARET BLISS (e-mail: blissmm0@sewanee.edu), **AMBER SMITH** (e-mail: smithal0@sewanee.edu), and **KRISTEN K. CECALA**, Department of Biology, University of the South, 735 University Avenue, Sewanee, Tennessee 37383, USA (e-mail: kkcecala@sewanee.edu).

NOTOPHTHALMUS VIRIDESCENS **(Eastern Newt). SIZE AT METAMORPHOSIS.** Body size at metamorphosis is an important determinant of future success in amphibians (e.g., Semlitsch et al. 1988. Ecology 69:184–192). Due to climate, resource availability, and regional variation, size at metamorphosis and growth can vary widely throughout the range of *Notophthalmus viridescens* (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 587 pp.). We observed growth rates and size at metamorphosis of *N. viridescens* from a large constructed, permanent pond in an understudied region on the southern Cumberland Plateau near Sewanee, Franklin Co., Tennessee, USA (35.2095°N, 85.9317°W; WGS 84). This pond has served as a source population for previous studies on *N. viridescens* physiology (e.g., Berner et al. 2013. J. Herpetol. 47:466–470). Surveys were conducted approximately every 10 days beginning 28 May 2014 and included dipnetting and visual observations of the pond shoreline. We observed recent hatchlings on 9 June 2014 as small as 9 mm SVL. We collected 28 individuals on 09–12 June 2014 with SVL ranging from 9 to 19 mm suggesting wide variation in timing of hatching. We did a second collection on 19–21 June 2014 of 334 individuals with SVL ranging from 9 to 21 mm. Our first observations of a metamorphic *N. viridescens* individual occurred on 03 July 2014, and we captured 14 metamorphic individuals from 3 July 2014 – 1 September 2014. The SVL at metamorphosis of these individuals ranged from 15 to 20 mm with a mean of 17.6 ± 0.50 mm SVL. Nine individuals marked with visible implant elastomer on 19 June 2014 (334 marked in total) and recaptured from 15 July–01 September 2015 exhibited mean growth rates of 0.15 ± 0.072 mm/day. These values represent the smallest metamorphic *N. viridescens* described in the

literature. In conclusion, *N. viridescens* in Sewanee, Tennessee, USA exhibit a distinct eft life stage, slow growth rates, and small sizes at metamorphosis.

LINDSEY A. LILES (e-mail: lilesa0@sewanee.edu) and **KRISTEN K. CECALA** (e-mail: kkcecala@sewanee.edu), Department of Biology, Sewanee: University of the South, 735 University Avenue, Sewanee, Tennessee 37383, USA.

***PLETHODON CINEREUS* (Eastern Red-backed Salamander). COLORATION.** The salamander *Plethodon cinereus* is an abundant species that exhibits two primary color variations (Redback and Leadback), which occur throughout eastern North America (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington D.C. 587 pp.). Erythrism, leucism, albinism, iridism, amelanism, and melanism are also known for this species, as are varying degrees of intermediacy for each morph (Moore and Oulett 2014. Can. Field Nat. 128:250–259). Herein, I report an observation of a poorly known color morph of *P. cinereus* that has only been mentioned in passing in the peer-reviewed literature, and for which a published image does not exist (Moore and Oulett 2014, *op. cit.*).

On 11 April 2015, at Buttermilk Falls State Park, Tompkins Co., New York, USA (42.4129°N, 76.5262°W; WGS 84), I found an adult *P. cinereus* of unknown sex that exhibited unusual coloration; the salamander was found under a stone on a steep WNW-facing hillside. The dorsal stripe of this specimen was white with occasional melanophores, uniform in shape, and clearly defined (Fig. 1.), while the sides and venter were normally colored. No red pigment could be found on the dorsal stripe upon close examination. This specimen can be distinguished from a partially leucistic individual by a lack of blotching of the white coloration, by the normally colored venter, and the presence of flecking on the sides. Thus, it seems to represent a variation of the abundant Redback morph. Subsequent surveys at this site failed to locate further specimens of *P. cinereus* with similar coloration, but typically patterned individuals of both the striped (Redback) and unstriped (Leadback) morphs were found in abundance.

FIG. 1. Dorsal view of the white-striped color variant of *Plethodon cinereus*.

I thank Kraig Adler for helpful comments on drafts of this note.

ELI HAINES-EITZEN, P.O. Box 133, Brooktondale, New York 14817, USA; e-mail: eli.haines.eitzen@gmail.com.

***SIREN INTERMEDIA* (Lesser Siren). LIMB REGENERATION.** Current hypotheses regarding the evolution of epimorphic regeneration capacity in vertebrates include a variety of explanations as to why some taxa are capable of limb regeneration while others lack such restorative survival mechanisms. General phylogenetic trends in the distribution of regeneration capacity include a negative correlation between regeneration capacity and animal maturity/size as well as a positive correlation between regeneration capacity and theorized selective pressure (Goss 1969. Principles of Regeneration. Academic Press Inc., New York. 278 pp.; Reichman 1984. Am. Nat. 123:752–763). In a previous review of amphibian regeneration capacity, it was reported that one family of salamanders, Sirenidae, lacked this restorative mechanism. Moreover, this same review noted specifically that *Siren intermedia* exhibits "no apparent regenerative ability to the capacity to produce a heteromorphic regenerate" (Scadding 1977. J. Exp. Zool. 202:57–68). This conclusion fit nicely into the observed trends mentioned above; an aquatic species propelled by undulation would have little selective pressure to regenerate forelimbs and *S. intermedia* is well above the size boundary previously correlated to lack of regeneration.

Contrary to the initial study and general trends noted above, we provide the first report of epimorphic limb regeneration in *S.*

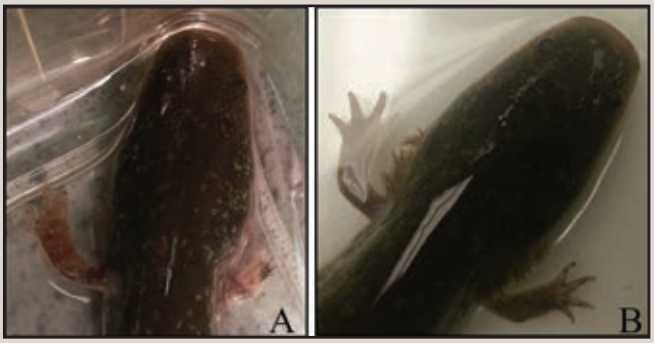

FIG. 1. Photographs of a Lesser Siren (*Siren intermedia*) right forearm regeneration progress at (A) 3 weeks and (B) 25 weeks after initial recorded observation

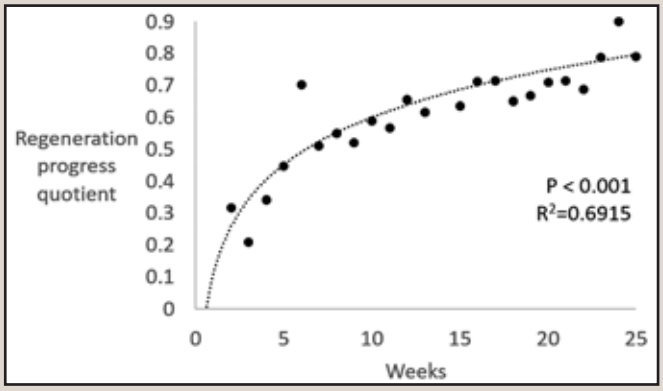

FIG. 2. Regeneration progress of an amputated forearm in a *Siren intermedia* over 25 weeks. Regeneration progress has been estimated by the quotient of the regenerating forearm area divided by the normal forearm area.

intermedia. In late summer 2014, two individual *S. intermedia* were collected from their native habitat in northern Florida (exact time and location unknown). The individuals were shipped to Nebraska Wesleyan University to be used as display specimens in early September 2014. Both individuals measured ca. 25 cm in length. After arrival, it was noted that the right forearm was amputated distal to the elbow (the time and cause of amputation is unknown) in one of the individuals. After observing unexpected digit formation with stump remodeling several weeks later, observations were recorded. Along with observations, quantitative regeneration progress and growth rate were estimated over 6 months. At one-week intervals, digital photographs were taken directly above the individual with the two limbs spread out flat within a tray of shallow water (Fig. 1). Areas of each forearm were estimated using ImageJ software and the relative area of the regenerating forelimb was plotted with respect to time in weeks (Fig. 2). The regenerating forearm grew (i.e., increased in area) at an average of +2.0% per week compared to growth of the non-amputated, normal limb. This observation calls for further regeneration studies of *S. intermedia*, re-evaluation of the regeneration capacity of the entire family Sirenidae, and suggests potential revision of observed general trends.

ANURA — FROGS

***ADENOMUS KELAARTII* (Kelaart's Dwarf Toad). PREDATION.** Amphibians have been recorded being predated by other vertebrates, including other amphibians (Toledo et al. 2007. J. Zool. 271:170–177), as well as invertebrates (Toledo 2005. Herpetol. Rev. 36:395–400) and carnivorous plants (Duellman and Trueb 1994. Biology of Amphibians. John Hopkins University Press, Baltimore, Maryland. 670 pp.). Among the invertebrates recorded preying on amphibians, attacks by Araneae spiders are quite well documented (Menin et al. 2005. Phyllomedusa 4:39–47). Although Menin et al. (2005. *op cit.*) reviewed such phenomena in amphibians in the Neotropics, with a special attention on the Central Amazonia and the Order Araneae, such records from the Paleotropics remain scarce. The only published accounts of invertebrates predating adult amphibians in Sri Lanka involve the huntsman spider (Bambaradeniya 2001. Lyriocephalus 4:140) and coleopteran larvae (De Silva et al. 2009. Froglog 91:5–7). Contributing to above knowledge, herein, we report the first ever observation from Sri Lanka of an *Adenomus kelaartii* (Kelaart's Dwarf Toad) being predated and fed upon by a huntsman spider of the genus *Heteropoda* (Fig. 1). The observation was made at 2224 h on 14 March 2015 during dry weather, on a rock outcrop of a fast flowing stream bank in Hunuwela Rubber Estate, Ratnapura District, Sri Lanka (6.6366°N, 80.6005°E, WGS 84; 266 m elev.). The site is surrounded by well grown evergreen forests including rubber and tea plantations and is close to the southern slope of the central hills.

The spider was observed to grip the sub-adult toad from the posterior end with its chelicerae together with the aid of the palpus. Although the toad made several escape attempts, the spider was able to held its prey steadily using sticky webs. The immobilization effect of the spider venom was fast, resulting in the frog showing no more reaction within the course of a few minutes. The Bufonid genus *Adenomus* is endemic to Sri Lanka (Manamendra-Arachchi and Pethiyagoda 1998. J. S. Asian Nat. Hist. 3:213–248) and includes only three species: *A. kelaartii* (listed as Endangered on the IUCN Red List), *Adenomus kandianus* (Kandy Dwarf Toad), and *Adenomus dasi* (Das' Dwarf Toad), both of which are Critically Endangered (Manamendra-Arachchi and Meegaskumbura 2012. *In* Weerakoon and Wijesundara [eds.], The National Red List 2012 of Sri Lanka, pp. 92. Ministry of Environment, Colombo, Sri Lanka). Seventeen more individuals of *A. kelaartii* were recorded from the same location along a 50 m transect of the stream over a 30 min period using flash lights. Other amphibians recorded from the location included two endemic species: *Lankanectes corrugate* (Corrugated water frog) and *Pseudophilautus cavirostris* (Hollow snouted shrub frog).

FIG. 1. *Adenomus kelaarti* being preyed upon by a spider (*Heteropoda sp.*).

We thank Kanishka D.B. Ukuwela, D.M.S.S. Karunarathna, A.A.T. Amarasinghe and Ishara H. Wijewardhane for discussion and reference materials. Frank Starm and Ranil P. Nanayakkara for identifying the spider. The observation was made during a field session of the conservation project on two globally and nationally endangered dragonfly species: Rivulet Tiger (*Gomphidia pearsoni*), and Wijaya's Scissortail (*Microgomphus wijaya*). This project aims to enhance the watershed of Hunuwela Estate, Kahawatta Plantation, a project of ICUN Sri Lanka, funded by Dilmah Conservation.

THARAKA SUDESH PRIYADARSHANA (e-mail: tharakas.priyadarshana@gmail.com) and **SANDUN J. PERERA** (e-mail: sandun.perera@gmail.com; sandun.perera@appsc.sab.ac.lk), Department of Natural Resources, Faculty of Applied Sciences, Sabaragamuwa University of Sri Lanka, Belihuloya 70140, Sri Lanka.

***AGALYCHNIS CALLIDRYAS* (Red-eyed Treefrog). PARASITISM.** Ticks belonging to the genus *Amblyomma* have been documented parasitizing toads and reptiles. For example, *Rhinella marina* (Cane Toad) is a well-known host of *Amblyomma* (Lampo and Bayliss 1996. Parasitology 113:199–206). Guglielmone and Nava (2010. Zootaxa 2541:27–49) have recorded *Amblyomma rotundatum* on several additional species of the Bufonidae family: *Rhinella arenarum* (Argentine Common Toad), *Rhinella crucifer* (Crucifer Toad), *Rhinella granulosus* (Granular Toad), *Rhinella icterica* (Yellow Cururu Toad), *Peltophryne peltocephala* (Cuban Giant Toad), *Rhinella schneideri* (Cururu Toad) and *Anaxyrus terrestris* (Southern Toad). This same genus was found parasitizing *Atelopus varius* (Harlequin Frog) and *Atelopus zeteki* (Panamanian Golden Frog; Richards et al. 2006. Herpetol. Rev. 37:332–333). Besides bufonids, *Discoglossus pictus* (Painted Frog), *Spea*

FIG. 1. *Amblyomma* sp. parasitizing an adult female *Agalychnis callidryas* in Sarapiquí, Heredia, Costa Rica.

bombifrons (Plains Spadefoot), *Pipa pipa* (Suriname Toad), *Pelophylax esculentus* (Edible Frog), and *Eupemphix nattereri* (Cuyaba Dwarf Frog) are also known hosts of *Amblyomma* (Guglielmone and Nava 2010, *op. cit.*, Gambale et al. 2014. Herpetol. Bull. 130:22–23).

At 1700 h on 5 October 2012, during a field trip to Isla Verde Reserve, Sarapiquí, Heredia, Costa Rica (10.4357°N, 84.0446°W; WG S84), an *Agalychnis* adult female (SVL = 54.87 mm) was found on a plant from the Heliconiaceae family and was being parasitized by a tick of the genus *Amblyomma* (Fig. 1). I did not collect the frog or the tick but the external characters (especially the shape of the scutum) are similar to the nymphs of *Amblyomma*. This genus is the most widely distributed in lowland forests of Central America. In Costa Rica there are 24 species of *Amblyomma* recorded, of which *A. dissimile* is considered a parasite of amphibians and reptiles (Jiménez et al. 2015. Syst. Appl. Acarol. 20:471–477).

Although *A. callidryas* is relatively common and has been widely studied, little is known about their parasites, especially ectoparasites. This observation is the first record of a tick parasitizing a frog from the Hylidae family, and a new host record for the genus *Amblyomma*.

I thank S. Bermudez (The Gorgas Memorial Institute for Health Studies, Panamá City, Panamá) for confirming the tick identification.

KATHERINE GONZÁLEZ, Escuela de Ciencias Biológicas, Universidad Nacional, Heredia, Costa Rica; e-mail: kattygv.09@gmail.com.

***ATELOPUS HOOGMOEDI* (Harlequin Toad). PREDATION.** *Atelopus hoogmoedi* is a small diurnal anuran from Guyana, Suriname, French Guiana and Brazil (Frost 2015. http://research.amnh.org/herpetology/amphibia/index.html; 25 April 2015). Adults are colorful and their conspicuousness might serve as a warning to potential predators not to eat them, as harlequin frogs contain potent skin toxins (Rueda-Almonacid et al. 2005. Ranas Arlequines: Bogotá, Colombia, Serie Libretas de Campo, Conservación Internacional. 158 pp.). *Atelopus* juveniles are less aposematic but might be toxic. *Leptodactylus mystaceus* (Common Toad-Frog, Sapo-rana Comun) is a large species of the *Leptodactylus fuscus* group, distributed throughout Brazil, occurring from the southern Amazon basin to Paraná (Affonso et al. 2011. Check List 7:198–199).

FIG. 1. A) *Leptodactylus mystaceus* preying upon a juvenile *Atelopus hoogmoedi*; B) dead regurgitated *Atelopus* juvenile.

Herein we report an opportune observation of an adult *L. mystaceus* preying upon a juvenile *A. hoogmoedi*. The predation occurred at 1025 h on 19 May 2014 in upland forest at Reserva de Desenvolvimento Sustentável Iratapuru, municipality of Laranjal do Jari, Amapá State, Brazil (0.3599°S, 52.0935°W, WGS 84; 108 m elev.). The ingestion of *A. hoogmoedi* must have started headfirst as by the time of our observation only the hind legs were visible (Fig. 1a). A few minutes later, the *L. mystaceus* regurgitated the juvenile *A. hoogmoedi* (Fig. 1b). After predation, the *L. mystaceus* was observed for one hour to check for any ill effects, and we noted none. This is the first report of *L. mystaceus*, a primarily nocturnal species, feeding on a diurnal anuran. The presence of numerous post-metamorphic and juvenile *A. hoogmoedi* on the day of observation suggests that *L. mystaceus* may have a generalist diet (Camera et al. 2014. Herpetol. Notes 7:31–36), consuming prey that is commonly available. Our observation may also suggest presence and effectiveness of toxicity in *A. hoogmoedi*, although the juvenile was dead after the predation attempt.

RUBENILSON OLIVEIRA PINTO and **CARLOS E. COSTA-CAMPOS**, Laboratório de Herpetologia, Departamento de Ciências Biológicas e da Saúde, Universidade Federal do Amapá, Campus Marco Zero do Equador, 68.903-419, Macapá, AP, Brazil (e-mail: eduardocampos@unifap.br).

***HYLA CINEREA* (Green Treefrog). PREDATION.** Arachnid species have frequently been documented to feed on anurans (Neil

FIG. 1. *Dolomedes triton* subduing *Hyla cinerea.*

1948. Herpetologica 4:158; Raven 1990. Mem. Queensland Mus. 29:448; Steehouder 1992. Litteratura Serpentium 12:71). According to a cursory literature review of invertebrates and their anuran prey (Toledo 2005. Herpetol. Rev. 36:395–400), *Hyla cinerea* has been preyed upon by the spider species *Dolomedes okefinokensis* (Okefenokee Fishing Spider; Jeffery et al. Herpetol. Rev. 35:158) and *Acanthepeira stellata* (Starbellied Orbweaver). At 2150 h on 17 August 2015 a *Dolomedes triton* (Six-spotted Fishing Spider) was observed grasping a juvenile *H. cinerea* and trying to subdue it (Fig. 1). The spider was perched on a reed in a water-filled ditch alongside County Road 414, 0.2 km S of Jonesboro, Craighead Co., Arkansas, USA (35.7559°N, 90.7048°W; WGS 84). *Dolomedes triton* has been observed feeding on adult *Acris gryllus* (Southern Cricket Frog; Graham and Sorrel 2009. Herpetol. Rev. 40:198) and larval *Lithobates catesbeianus* (American Bullfrog; Rogers 1996. Herpetol. Rev. 27:75) in Alabama.

JOHN D. KONVALINA (e-mail: john.konvalin@smail.astate.edu) and **STANLEY E. TRAUTH**, Department of Biological Sciences, Arkansas State University P.O. Box 599, State University, Arkansas 72467, USA (e-mail: strauth@astate.edu).

***LEPTODACTYLUS KNUDSENI* (Pepper Frog). DIET.** Leptodactylids are frogs known as sit-and-wait predators that consume several different types of arthropods (Toft 1980. Oecologia 47:34–38; Solé et al. 2009. Herpetol. Notes 2:9–15; Sugai et al. 2012. Biota Neotro. 12:99–104; Camera et al. 2014. Herpetol. Notes 7:31–36). The prey is often swallowed whole since anurans do not chew food, limiting the size of the prey they can eat (Lima and Moreira 1993. Oecologia 95:93–102).

Leptodactylus knudseni is a large (SVL = 113–135 mm), nocturnal frog generally found on the forest floor in riparian habitat (Lima et al. 2008. Guide to the Frogs of Reserva Adolpho

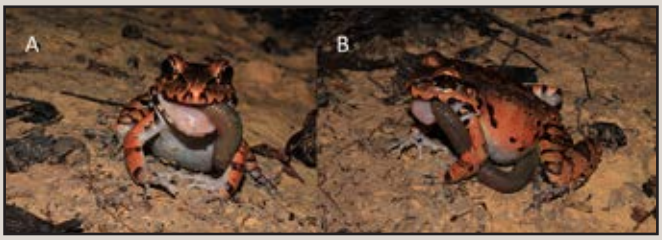

FIG. 1. A) *Leptodactylus knudseni* swallowing the giant worm, *Rhinodrilus priolli.* B) During our presence the frog stopped swallowing the worm and it began crawling out of the frog's mouth.

Ducke, Central Amazonia. Attema Design Editorial, Manaus. 168 pp.). *Rhinodrilus priolli* (Giant Earthworm) is one of the largest terrestrial invertebrates known in the world reaching over 2 m in length (Lang et al. 2012. Am. Midl. Nat. 167:384–395). At 0130 h on 30 April 2012 at Fazenda Experimental da UFAM (2.6589°S, 60.0660°W; WGS 84), 38 km from Manaus, Amazonas, Brazil on Hwy BR174, we observed a male *L. knudseni* (SVL = 97.8 mm), swallowing a *R. priolli* which had a total length of 210 mm (Fig. 1). While we observed the frog feeding, it became inactive and started to regurgitate the worm. At the same time, the worm was crawling out of the frog's mouth. The worm was ingested headfirst but suffered little apparent damage despite having been nearly totally swallowed by the frog. The size of the worm may have prevented the frog from swallowing it.

ANDRÉ L. BARROS, Departamento de Ecologia, Instituto Nacional de Pesquisas da Amazônia – Campus V8, Av. ***PHYSALAEMUS NATTERERI* (Cuyaba Dwarf Frog). TADPOLE DIET.** The functional roles and trophic status of generalized tadpoles are poorly understood (Altig et al. 2007. Freshwater Biol. 52:386–395). At 2030 h on 27 November 2014 at the Reserva Natural de Laguna Blanca, Departamento San Pedro, Paraguay (23.8127°S, 56.2949°W; WGS 84), I encountered a small ephemeral pond (ca. 3 m × 3 m) where I observed dozens of *Physalaemus nattereri* tadpoles consuming the flesh of the seeds of a Coco Palm (Family Arecaceae). In the same pond, I also observed several of the same seeds that had already been cleared of their flesh. To my knowledge, this is the first time that *P. nattereri* tadpoles have been observed consuming the flesh of the seeds of Coco Palms. In a study of their diet in southeastern Brazil, tadpoles of *P. nattereri* that occurred in both temporary and permanent ponds had large proportions of plant fragments, euglenids, algae, and diatoms in their diet (Do Prado et al. 2009. S. Am. J. Herpetol. 4:275–285). While it was not specified as to the type of plant fragments found in the diet of *P. nattereri* in Brazil, my observation is consistent with the previous report that plant material is a component in the diet of *P. nattereri* tadpoles.

CHRISTOPHER M. SCHALK (e-mail: cschalk@tamu.edu), Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA.

***PRISTIMANTIS REICHLEI*. EYE COLORATION.** Among anurans, eye color is used as a reliable taxonomic character (Lynch and Duellman 1997. Univ. Kansas Nat. Hist. Mus. Spec. Publ. 23:1–236). This is a useful tool for the frogs in the genus *Pristimantis* where external morphology is highly variable across species groups and conservative in assemblages, and few reports show eye color variation (Duellman and Lehr 2009. Terrestrial-breeding frogs (Strabomantidae) in Peru. NTV Science, Münster, Germany. 382 pp.). *Pristimantis reichlei* was first described as having a metallic yellow-to-orange iris with a transverse bold black stripe (Padial and De la Riva 2009. Zool. J. Linn. Soc. 155:97–122) and this pattern is commonly found throughout its range (Melo-Sampaio and Souza 2009. Check List 6:385–386).

On 11 September 2009 at Fazenda Experimental Catuaba, municipality of Senador Guiomard, Acre, Brazil (10.0822°S, 67.0626°W, WGS 84; 180 m elev.), I observed, photographed, and collected an individual of *P. reichlei* (UFAC-RB 4594) with an unusual pattern of eye coloration. The eye was metallic silver in upper half of the iris, the center was tan, with less silver coloration in the lower part (Fig. 1). Other individuals from this site displayed typical diurnal and nocturnal eye coloration as described in Padial and De la Riva (2009, *op. cit.*) and Melo-Sampaio and Souza (2009, *op. cit.*). Although eye coloration is a useful diagnostic character in the genus *Pristimantis* and this variation appears to be rare, this fact should be evaluated within species accounts and/or descriptions.

FIG. 1. *Pristimantis reichlei* showing unusual eye coloration.

PAULO ROBERTO MELO-SAMPAIO, Programa de Pós-graduação em Zoologia - Museu Nacional, Quinta da Boa Vista s/n – Rio de Janeiro, RJ - CEP: 20940-040, Brazil; e-mail: prmelosampaio@gmail.com.

***RHINELLA ARENARUM* (Argentine Toad). EGG PREDATION BY LEECHES.** Leech predation on amphibians has been previously reported (Moore 1953. Not. Nat. Acad. Nat. Sci. Philadelphia 250:1–13; Cargo 1960. Chesapeake Sci. 1:119–120; Loebmann et al. 2008. Amphibia 7:31–34; Alvarez 2010. Bol. Asoc. Herpetol. Esp. 21:25–26; Tiberti and Gentilli 2010. Acta Herpetol. 5:255–258). Amphibian egg predation by leeches has been reported in North and South America, Southeast Asia, Australia, and Europe (Burgin and Schell 2005. Acta Zool. Sinica 51:349–353; Gunzburger and Travis 2005. J. Herpetol. 39:547–571; Romano and Di Cerbo 2007. Acta Zool. Sinica 53:750–754; Soler et al. 2014. Cuad. Herpetol. 28:39–41). Previous reports of anuran eggs being predated by leeches in Argentina include an unidentified *Oxyptychus* feeding on eggs of *Rhinella dorbignyi* (Dorbigny's Toad) and *Hypsiboas pulchellus* (Montevideo Treefrog; Soler et al. 2014. *op. cit.*).

FIG. 1. Specimens of *Oxyptychus striatus* collected in the observation area.

Herein we report a case of egg predation on at least two clutches of *Rhinella arenarum* by the leech *Oxyptychus striatus* (Ringuelet 1945. Fauna de agua dulce de la Republica Argentina. Volumen XVII Annulata, Fasciculo 1 Hirudinea. pp. 225–232; Fig. 1). The observations were made in a very slow flowing stream in San Luis, Departamento Conlara, Ruta Provincial 5, 15 KM NW Santa Rosa del Conlara, Argentina (32.2567°S, 65.3214°W, WGS 84, 717 m elev.), at ~2300 h on 19 January 2013. Several leeches (reference voucher specimens MACN-In 40169) were attached with their sucker to the gelatinous egg strings, surrounding and penetrating them with their mouths at the point where each egg was found (Fig. 2). After the eggs were consumed, the string was left completely empty (Fig. 3). Once each egg was consumed, the leech left a characteristic cylindrical projection perpendicular to the longitudinal axis of the string, as if the jelly was everted by the leech's mouth once it finished feeding on the egg (Fig. 3).

Oxyptychus is a hirudiniform genus of leeches with seven species distributed in Puerto Rico, Panama, Ecuador, and east of the Andes to the north of the extra-Andean Patagonia. Though they feed mainly on the blood of their hosts (Ringuelet 1945. *op. cit.*), recent observations suggest that they also prey on their eggs (Soler et al. 2014. *op. cit.*; present observation). Several similar cases have been observed among hirudiniforms: *Macrobdella ditetra* consumes blood and eggs of frogs (Moore 1953. *op. cit.*), and *M. diplotertia* has been observed attacking tadpoles and simultaneously consuming the eggs of *Lithobates clamitans* (Green Frog) and *L. sphenocephalus* (Southern Leopard Frog) (Turbeville and Briggler 2003. J. Fresh. Ecol. 18:155–159). Hirudiniform leeches lack a proboscis, and to feed they employ their jaws to tear the skin of the host. In the case of egg predation, they manage to bypass the gelatinous capsules surrounding the eggs, perforating them with their jaws. There are different known ways to achieve this: (a) the leech *Bassianobdella fusca* specializes on this type of food, for which it enters the foam nest, then surrounds the egg using its ventral surface and swallows it

FIG. 2. An individual of *Oxyptychus striatus* surrounding egg strings of *Rhinella arenarum*.

FIG. 3. Arrangement of egg strings of *Rhinella arenarum* with perpendicular eversions of the egg jelly (the arrow indicates one of these eversions).

wholly (Burgin and Schell 2005. *op. cit.*), and (b) *M. diplotertia* begins investigating the eggs with its head, and once it chooses an egg, it extends its body and secures its sucker to the gelatinous capsule of another egg to enter the selected one, and once inside, surrounds the egg and consumes it (Trauth and Neal 2004. J. Ark. Acad. Sci. 58:139–141).

Most bufonids have toxins (bufadienolides) from the egg stage to adulthood. The diversity and concentration of these molecules varies during ontogeny: the eggs contain the most toxin, with toxicity decreasing during larval development and increasing again after metamorphosis. The surrounding jelly coat that protects the eggs from predators lacks these toxins (Hayes et al. 2009. J. Chem. Ecol. 35:391–399). In Australia, deaths of native species of turtles and fish were reported after consuming eggs of *Rhinella marina* (Cane Toad) and, to a lesser extent, its tadpoles (Greenlees and Shine 2011. Austral Ecol. 36:53–58). Insects can also find the early stages of toads unpalatable: cases where Odonata larvae preferred not to consume tadpoles of *Rhinella spinulosa papillosa* (Sapo Espinosus) have been recorded (Jara and Perotti 2006. Cuad. Herpetol. 19:37–42). In contrast, Dytiscidae beetles prefer *R. marina* tadpoles to native Australian tadpoles or fish (Cabrera-Guzmán et al. 2012. Biol. Cons. 153:1–9). However, there are reports of leeches that apparently are not affected by these toxins and consume eggs and tadpoles of bufonids (see revisions of Gunzburger and Travis 2005. *op. cit.*; Romano and di Cerbo 2007. *op. cit.*). Nevertheless, there are also cases where other species of leeches have been affected by these toxins, such as *Goddardobdella elegans* where the survival rate was significantly reduced after feeding on tadpoles of *R. marina* (Crossland and Alford 1998. Aust. J. Ecol. 23:129–137). In that same study, other invertebrates did not suffer lethal effects after consuming eggs or tadpoles. Litch (1969. Am. Midl. Nat. 82:296–298) also reported unpalability of eggs of *Anaxyrus boreas* (Western Toad) by *Haemopsis* sp., showing a high aversion to egg compounds.

Leeches of the genus *Oxyptychus* are likely natural predators of *Rhinella*. The specific mechanism that allows these leeches to tolerate the toxicity of egg compounds so that they may be consumed safely is unknown.

We acknowledge Gustavo, Ramiro, and Rodrigo Carrizo for their help in the field. We also thank Cristina Damborenea and Hugo Merlo Alvarez (Museo de La Plata) for permission to work with vouchers under their care, and Alejandro Tablado (División Invertebrados, MACN). ***RHINELLA SCHNEIDERI* (Cururu Toad). EPIBIOSIS.** Epibiosis is a facultative relationship between an epibiont and a basibiont (Wahl 1989. Mar. Ecol. Prog. Ser. 58:175–189). The term epibiont is used to designate individuals that colonize a free-living substrate and the term basibiont is used to describe individuals that host the epibiont (Taylor 2002. Palaios 17:522–525). Reports of tadpoles as basibionts in Brazil are very scarce, with only two published accounts, both for the toad *Rhinella crucifer* (Striped Toad) in Juiz de Fora municipality, Minas Gerais state, in the Atlantic Forest biome (Dias et al. 2009. Parasitol. Int. 58:471–474; Fernandes et al. 2011. Zoologia 28:777–783). Both studies identified the tadpoles involved as *Rhinella pombali* (Pombal's Toad), however Thomé et al. (2012. BMC Evol. Biol. 12:242) considered *R. pombali* a hybrid of *R. crucifer* and *R. ornata*, rather than a valid species. Accordingly, toads previously assigned to *R. pombali* are now considered to be either *R. crucifer* or *R. ornata*, depending on the locality. According to Frost (2015. http://research.amnh.org/vz/herpetology/amphibia; 23 Aug 2015), populations from Minas Gerais state should be considered *R. crucifer*. Ciliates of the genus *Trichodina* are reported as epibionts of many amphibian and fish species (Kreier and Baker 1991. *In* Sleigh [ed.], The Nature of Protozoa, pp. 1–53. Academic Press, San Diego; Xu et al. 1999. Syst. Parasitol. 42:229–237). Trichodinids mostly feed on bacteria present on tadpole skin mucous, but not from the host skin itself (Collymore et al. 2013. Comp. Med. 63:310–312). Possible pathogenic disturbance in amphibians might occur due to the spinning movements of attached ciliates in high intensity infestations, possibly causing tegument damage of the epithelial cells (Poynton and Whitaker 2001. *In* Wright and Whitaker [eds.], Amphibian Medicine and Captive Husbandry, pp. 193–221. Krieger Publishing Company, Malabar, Florida; Zanolo and

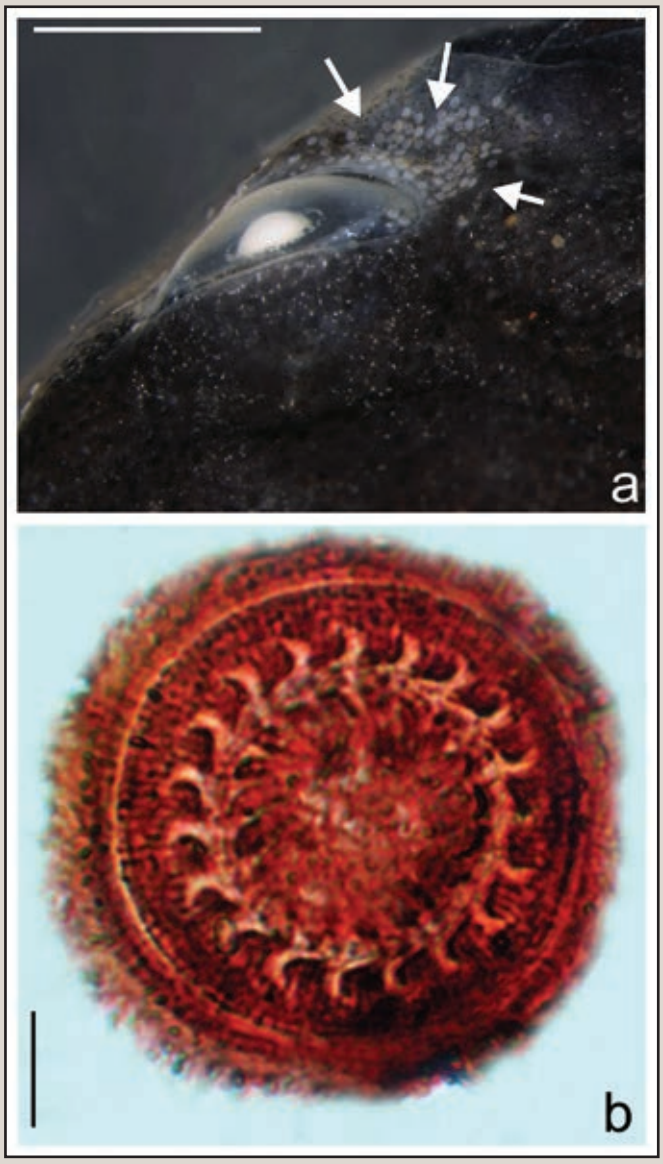

FIG. 1. A) View of the eye of the tadpole *Rhinella schnederi*. Arrows indicate an area with great abundance of ciliates. Scale bar = 1 mm. Photo credit to Fausto Nomura. B) *Trichodina* sp. revealed by dry silver impregnation technique. Scale bar = 10 µm.

Yamamura 2006. Semin. Ci. Agr. 27:281–288). Ciliates that belong to the subclass Peritrichia, such as those in the genus *Trichodina*, are mostly tolerant to pollution, being abundant in organically enriched freshwater ecosystems with high bacterial densities (Kuskoa and Watabe 1987. Oecologia 73:16–20). The presence of a high infestation of these protozoa on the surface of an organism may reflect poor water quality (Collymore et al. 2013. Comp. Med. 63:310–312). According to Palma and Dobberstein (1999. Parasitol. Res 85:726–732) the abundance of *Trichodina* sp. can indicate not only the health status of the host but also the eutrophication level of the environment.

Rhinella schneideri is a common toad species in the Cerrado biome in central Brazil and is widely distributed throughout Brazil, Paraguay, Bolivia, Argentina and Uruguay, occurring in forested and urban areas (Pramuk 2006. Zool. J. Linn. Soc. 146:407–452; Frost 2015. http://research.amnh.org/vz/herpetology/amphibia; 22 June 2015). The larval period is relatively short, lasting ca. two months (Barreto and Moreira 1996. J. Herpetol. 30:87–92). Here, we report an epibiotic relationship of *Trichodina* sp. infesting tadpoles of the species *R. schneideri*.

On 28 October 2014 and 21 November 2014, 50 tadpoles of *R. schneideri* were collected from ponds in two urban parks: Liberdade (16.6498°S, 49.2346W; WGS 84) and Beija-Flor (16.6526°S, 49.2315°W, WGS 84), both located in Goiânia municipality, state of Goiás, Central Brazil. In the laboratory, we detected ciliates on some of the tadpoles, especially around the eyes (Fig. 1A) and on the tail base. The ciliates were screened and submitted to a dry silver impregnation technique (Klein 1958. J. Protozool. 5:99–103) for analysis of essential structures that allowed the identification of the ciliate as belonging to the genus *Trichodina* (Fig. 1B). The prevalence of infestation was 38%. Tadpole vouchers were housed at the Coleção Zoológica da Universidade Federal de Goiás (ZUFG), Goiânia, Goiás, Brazil (ZUFG 2671). There are few studies on epibiotic relationships between tadpoles and ciliates; more research is required for a better understanding of the relationship dynamics. This note represents the first documentation of the epibiotic association between *Trichodina* sp. and *R. schneideri* as well the first report of this relationship for the Cerrado biome.

Collections occurred under the authorization of SISBIO #46983-1. We acknowledge Fausto Nomura for taking the tadpole photograph.

TESTUDINES — TURTLES

***CARETTA CARETTA* (Loggerhead Sea Turtle). DIET.** Loggerhead Sea Turtles have the most diverse diet among marine turtles with 178 items registered from 14 phyla, with strong spatial and ontogenetic variations (Dodd 1988. US Fish Wildlife Service Biological Report 88, 110 pp.). There are also temporal changes in diet (Plotkin et al. 1993. Marine Biol. 115:1–15). Diet analysis of 52 Loggerhead Sea Turtles collected as bycatch from 1990 to 1992 demonstrated that these turtles fed predominantly at the surface (Parker et al. 2005 Fish. Bull. 103[1]:142–152). Shifts in diet between 1983 to 2002 have been documented, suggesting that declines in horseshoe crab and blue crab populations have caused Loggerheads to forage in nets or on discarded fishery bycatch (Seney and Musick 2007. Copeia 2007:478–489).

During two field trips in 2014 we collected food samples from the esophagi of 25 *Caretta caretta* (body mass 10–25 kg, and straight carapace length [SCL ± 0.1 cm] 47–71 cm; mean SCL = 59 ± 5 cm) captured at Golfo the Ulloa (25.98777°N, 112.976666°W and 25.98944444°N, 112.71666666°W; WGS 84) located in Bahía Magdalena, Baja California Sur, Mexico.

In all the samples a combination of squat lobster (*Plereucodes planipes*), octopus (*Octopus hubbsorum*), squid (*Loligo* sp.), and fish bones (most likely sardines) were present and comprised 80% of the total volume. To our knowledge, this is the first report of targeted squat lobster, octopus, squid, and fish consumption by *Caretta caretta*. The fact that squat lobster, octopus, squid, and fish occurred in such high proportion among a substantial number (80%) of turtles suggests that this new diet

combination is a major food resource for these turtles at Golfo de Ulloa. It also supports an earlier suggestion that benthic prey were common in small turtles (< 26 cm SCL) and more oceanic prey were used by larger animals (Casale et al. 2008. Mar. Ecol. Prog. Ser. 372:265–276). We thank CONANP and PROFEPA for their assistance in the logistics of field work.

RAFAEL RIOSMENA-RODRIGUEZ and **MARIA MONICA LARA-UC**, Programa de Investigación en Botánica Marina, Departamento de Biología Marina, Universidad Autónoma de Baja California Sur, Km 5.5 Carretera al Sur, La Paz B.C.S. 23080,Mexico (e-mail: riosmena@uabcs.mx).

***CHELONIA MYDAS AGASSIZII* (East Pacific Green Sea Turtle). DIET.** The East Pacific Green Sea Turtle is considered the most carnivorous of all Green Sea Turtle subpopulations worldwide (Bjorndal 1997. *In* Lutz and Musick [eds.], The Biology of Sea Turtles, pp. 199–231. CRC Press, Boca Raton, Florida). Novel Green Sea Turtle diet items have been reported, including the Sea Pen, *Ptilosarcus undulatus* (Seminoff et al. 2002. Copeia 2002:266–268), pelagic red crabs, *Pleuroncodes planipes* (Lopez-Mendilaharsu et al. 2005. Aquat. Conserv. Mar. Freshwater Ecosyst. 15:259–269), tunicates and crustaceans (Amorocho and Reina 2007. Endang. Species Res. 3:43–51), hydrozoans, scyphozoans, nematodes, annelids, mollusks (Carrion-Cortez et al. 2010. J. Mar. Biol. Assoc. U.K. 90[5]:1005–1013), sponges, *Craniella* sp. and *Suberites aurantica* (Rodriguez-Baron 2010. MS thesis. Centro Interdisciplinario de Ciencias Marinas [CICIMAR-IPN]. 98 pp.), and the anemone *Palythoa ignota* (Rodriguez-Baron et al. 2011. Herpetol. Rev. 42:416).

It has been suggested that such dietary diversity is a response to the energy requirements of these animals in the early life stages, facilitating nutritional (e.g., protein) gains for development and maturation (Bjorndal 1985. Copeia 1985[3]:736–751) and optimizing digestion time (Amorocho and Reina 2008. J. Exp Mar. Biol. Ecol. 360:117–124). It has also been noted that *C. mydas* diet is influenced by resource availability (Balazs 1980. NOAA Tech. Memo. NOAA-TM-NMFS-SWFS-7; Garnett et al. 1985. Wildl. Res. 12:103–112) and that diet selection is linked to the composition and capacity of the hind-gut microflora, which may change as turtles grow and/or occupy different habitats (Bjorndal 1980. Mar. Biol. 56:147–154).

During two field trips in 2014 we collected food samples from the esophagi of 17 Green Sea Turtles (body mass 8–20 kg, and straight carapace length [SCL ± 0.1 cm] 43–45 cm; mean SCL = 85 ± 4 cm) captured at Golfo the Ulloa (25.59166°N, 112.58361°W and 25.59222°N, 112.43°W) located in the Bahía Magdalena, Baja California Sur, Mexico. A combination of octopus (*Octopus hubbsorum*), squid (*Loligo* spp.), and fish bones (most likely sardines) were present in all the samples and comprised 70% of the total volume. Turtle mean body condition index (BCI) was 1.45 (range = 1.30–2.10), similar to the values reported in previous studies (Koch et al. 2007. Mar. Biol. 153[1]:35–46; Seminoff et al. 2003. J. Mar. Biol. Assoc. U.K. 83:1355–1362). To our knowledge, this is the first report of targeted octopus, squid, and fish consumption by *Chelonia mydas agassizii*. The fact that octopus, squid, and fish occurred in such high proportion among a substantial number (70%) of turtles suggests that this diet combination is a major food resource for these turtles at Golfo de Ulloa, and that Green Sea Turtles have the capacity to assimilate nutrients from these invertebrate and fish species (Bjorndal 1990. Bull. Mar. Sci. 47[2]:567–570). We thanks CONANP and PROFEPA for their assistance in the logistics field work.

MARIA MONICA LARA-UC and **RAFAEL RIOSMENA-RODRIGUEZ,** Programa de Investigación en Botánica Marina, Departamento de Biología Marina, Universidad Autónoma de Baja California Sur,Km 5.5 Carretera al Sur, La Paz B.C.S. 23080,Mexico (e-mail: riosmena@uabcs.mx).

***CHRYSEMYS PICTA BELLII* (Western Painted Turtle). RECORD CARAPACE LENGTH.** *Chrysemys picta bellii* is the largest and one of the most geographically widespread subspecies of *C. picta*, reaching the northern extent of the species' range in western Canada (Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed. John Hopkins University Press, Baltimore, Maryland. 187 pp.). *C. picta bellii* exhibits sexual size dimorphism such that females attain larger carapace lengths than males.

On 2 June 2015 we captured a female *C. picta bellii* in Wascana Marsh in Regina, Saskatchewan, Canada, as part of a radio-telemetry project. The female weighed 2590 g and had a straight-line carapace length of 266 mm. To our knowledge, this is the largest documented carapace length for *C. picta bellii*. The previous record straight-line carapace length was 254 mm as documented by Ernst and Lovich (*op. cit.*), location unknown. Our observation was made in a population near the northern extent of the subspecies' range, where females have been found to mature later and attain larger body sizes than those in southern populations of the species' range (Moll 1973. Herpetologica. 20[4]:307–318; St. Claire et al. 1994. Can. J. Zool. 72:1436–1443).

***ERETMOCHELYS IMBRICATA* (Hawksbill Turtle). DIET.** *Eretmochelys imbricata* is distributed throughout the tropics where it fills an important ecological role consuming sponges that grow on coral reefs. Here we document *E. imbricata* consuming *Hermodice carunculata* (Bearded Fireworm), a prey item that to our knowledge has not been previously documented for this species. At 1400 on 19 September 2013, while scuba diving under the Frederiksted Pier in Frederiksted, St. Croix, US Virgin Islands, we witnessed a juvenile *E. imbricata* consume *H. carunculata*, which was located on the surface of the seafloor at a depth of approximately 9 m. The turtle consumed the worm in a single bite and did not show an aversion to having consumed it, even though *H. carunculata* possesses bristles that secrete neurotoxins. Before swimming out of view, the turtle continued to forage for 15 minutes on crustaceans that were growing on pier pylons.

Eretmochelys imbricata primarily consumes sponges that possess both physical and chemical defenses composed of toxic compounds and siliceous spicules (Meylan 1988. Science 239: 393–395). The species possesses a specialized digestive system that enables it to eat such prey, which is hazardous to many other animals. This ability to consume toxic items evidently also enables *E. imbricata* to consume polychaetes such as *H. carunculata* that possess chemical defenses. As one of the few species that can consume sponges, *E. imbricata* plays an essential role in preventing sponges from overpopulating reefs, thus helping to maintain reef biodiversity (Leon and Bjorndal 2002. Mar. Ecol. Prog. Ser. 245:249–258). Our observation suggests that *E. imbricata* might also aid in regulating numbers of other toxic invertebrates that have few natural predators.

JACOB HILL (e-mail: jearl.hill98@gmail.com) and **COURTNEY KING**, Carnivore Ecology Laboratory, Forest and Wildlife Research Center, Mississippi State University, Mississippi State, Mississippi 39762, USA

***GLYPTEMYS INSCULPTA* (Wood Turtle). NEST PREDATION.** *Glyptemys insculpta* is a riverine turtle species that inhabits the Great Lakes and New England regions of North America, ranging from eastern Minnesota to Nova Scotia (Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed. Johns Hopkins Univ. Press, Baltimore, Maryland. 827 pp.). Despite many known mammalian, avian, and reptilian predators (see Ernst and Lovich 2009, *op cit.*), to our knowledge predation by *Taxidea taxus* (American Badger) has not been documented. *T. taxus* is primarily found in the western and central portions of the United States (Long 1999. The Smithsonian Book of North American Mammals, Smithsonian Inst. Press, Washington, D.C., 750 pp.) The ranges of *G. insculpta* and *T. taxus* overlap in portions of Minnesota, Wisconsin, Michigan, Pennsylvania, and southern Ontario.

On 15 June 2015, we documented *G. insculpta* nest predation by two *T. taxus* in Minnesota (specific locations withheld in compliance with state of Minnesota data practices law). The nest predation events were captured by a camera trap (Browning Strike Force HD, BTC-5) from 1820 h until 1923 h, and from 2026 h to 2257 h. The two *T. taxus* dug in the sand where *G. insculpta* had recently laid eggs and consumed eggs that were found. Over 600 pictures captured the entire sequence of events, including an image taken at 1828 h showing *T. taxus* eating one of the excavated eggs (Fig. 1).

Nest predation by *T. taxus* was also documented at a separate site in Minnesota where *G. insculpta* stage and nest. At this site, *T. taxus* was observed digging in the sandy substrate and consuming turtle eggs on 4 June 2015 from 1151 h to 1201 h. Both nest predation sites have been known *G. insculpta* nesting locations since 1990 (Buech et al. 1997. *In* Proceedings: Conservation, Restoration, and Management of Tortoises and Turtles—An International Conference, pp. 389–391. New York Turtle and Tortoise Society, New York). Additional nest predators captured in pictures excavating nests at these nesting sites between May and July 2015 include *Procyon lotor* (Raccoon), *Mephitis mephitis* (Striped Skunk), *Corvus corax* (Common Raven), and *Corvus brachyrhynchos* (American Crow). Other potential nest predators whose presence was captured at nesting sites include *Urocyon cinereoargenteus* (Gray Fox) and *Lontra canadensis* (North American River Otter). *Chelydra serpentina* (Snapping Turtle) and *Chrysemys picta* (Painted Turtle) were also present and nesting in the vicinity. Between the two sites, at least 12 nests were predated within a week of being laid.

FIG. 1. *Taxidea taxus* predating recently laid *Glyptemys insculpta* eggs.

MADALINE M. COCHRANE (e-mail: cochr081@umn.edu) and **RON A. MOEN**, Natural Resources Research Institute, University of Minnesota-Duluth, 5013 Miller Trunk Highway, Duluth, Minnesota 55811, USA; **DONALD J. BROWN**, Department of Forest and Wildlife Ecology, University of Wisconsin-Madison, 1630 Linden Drive, Madison, Wisconsin 53706, USA.

***GOPHERUS POLYPHEMUS* (Gopher Tortoise). COYOTES DENNING IN GOPHER TORTOISE BURROW.** Gopher tortoises are ecosystem engineers and their burrows are used by a number of taxa including both invertebrate and vertebrate species (Speake 1981. *In* Lohoefener et al. [eds.], The Future of Gopher Tortoise Habitats, pp. 44–47. Proceedings 2nd Annual Meeting Gopher Tortoise Council. Florida State Museum, Gainesville). Over 360 species are known to use *G. polyphemus* burrows and consequently, it is considered to be a keystone species within its ecosystems (Eisenberg 1983. Proceedings of the 4th Annual Meeting of the Gopher Tortoise Council, pp. 1–4). *G. polyphemus* is a state threatened species in Georgia, is a candidate for federal listing in the eastern portion of its range, and is currently a federally listed threatened species in the western portion of its range (USFWS 2009. Federal Register 74:46401–46406).

In a Longleaf Pine (*Pinus palustris*)-dominated forest community at the Joseph W. Jones Ecological Research Center in Newton, Georgia, USA, we documented the use of *G. polyphemus* burrows by *Canis latrans* (Coyote). On 16 July 2012, we received a report of multiple *C. latrans* entering a *G. polyphemus* burrow. Upon investigation, we observed *C. latrans* tracks around the entrance and leading into the burrow. Trail camera photos confirmed the eyewitness account and field sign that a breeding pair of *C. latrans* were denning in the burrow with ≥ 2 pups. There was no evidence that *G. polyphemus* were still using the burrow. Given that coyotes are likely to feed upon many of the vertebrate and invertebrate species that inhabit burrows, including *G. polyphemus* (Moore et al. 2006. Herpetol. Rev. 37:78–79), we assumed the majority of the burrow's inhabitants had been displaced.

Canis latrans is considered a nonnative species in Georgia, having only recently entered the state presumably facilitated by anthropogenic factors; their impacts on native fauna is of great concern to wildlife managers. Although Coyote use of *G. polyphemus* burrows has been documented in the western portion of *G. polyphemus* range, these interactions are novel in Georgia where these species did not co-occur historically (Cox et al. 1987. Ecology and Habitat Protection Needs of Gopher Tortoise [*Gopherus polyphemus*] Populations Found on Lands Slated for Large-scale Development in Florida. Florida Game and Fresh Water Fish Commission Nongame Wildlife Program Technical Report No. 4, Tallahassee). *Canis latrans* might negatively influence *G. polyphemus* and associated burrow communities through direct predation and kleptoparasitism.

***MACROCHELYS APALACHICOLAE* (Apalachicola Alligator Snapping Turtle). AERIAL BASKING.** The Alligator Snapping

Turtle was recently split into three species (Thomas et al. 2014. Zootaxa 3786:141–165). Observations of basking *Macrochelys* are rare. Carr et al. (2011. IRCF Reptiles & Amphibians. 18:2–5) reviewed nine previously documented basking events and Elsey and Bourgeois (2014. Herpetol. Rev. 45:688–689) recently reported two additional observations. With the exception of Thomas (2009. Herpetol. Rev. 40:336), who reported on *M. suwanniensis* in the Suwannee River, Florida (*M. temminckii* at time of observation), all previously reported aerial basking observations were of *M. temminckii*. Here we report the first two aerial basking observations for the newly recognized *M. apalachicolae*.

On 13 May 2014 at 1603 h EPH and JDM observed an immature *M. apalachicolae* (estimated mass less than 4.5 kg) basking on the Choctawhatchee River, Holmes Co., Florida, USA. The turtle was perched on a willow trunk (*Salix* sp.) that was horizontal to the river surface. The turtle was located about 2 m out from the bank and approximately 0.5 m above the water. The turtle escaped into the water after a photo was taken. Air temperature was approximately 32°C under partly sunny skies.

A second immature *M. apalachicolae* (similar in size to the above) was observed basking by JDM at 1547 h on 21 May 2014 on the Apalachicola River, Liberty Co., Florida, USA. This turtle was perched more than 1 m above the water's surface at the top of a nearly vertical snag located 5 m out from the bank. The turtle was clinging to the snag with the head up, but upon detection it dropped into the river. Air temperature was approximately 32°C under mostly sunny skies.

JONATHAN D. MAYS (e-mail: jonathan.mays@myfwc.com) and **E. PIERSON HILL**, Florida Fish and Wildlife Conservation Commission, 1105 S.W. Williston Road, Gainesville, Florida 32601, USA (e-mail: pierson.hill@myfwc.com)

***PHRYNOPS TUBEROSUS* (Cotinga River Toad-headed Turtle). PREDATION.** Turtles and their eggs are predated by a wide variety of animals, including many species of mammals. Here we report predation on eggs and hatchlings of *Phrynops tuberosus* by reintroduced monkeys, *Sapajus libidinosus*, in Brazil.

Data was collected on an island (area approximately 8 ha) near the Mae D'Agua dam, municipality of Coremas, state of Paraíba, northeastern Brazil, within the caatinga biome (7.0694°S, 37.9525°W). This study was associated with "Project *Cebus*: Welfare and monitored reintroduction of capuchin monkeys," coordinated by UFRN and the Brazilian Wildlife Rescue Center from the Institute of Environment and Natural and Renewable Resources (CETAS-IBAMA). This project prepares rescued individual Brown Capuchin Monkeys (*Sapajus libidinosus*) for reintroduction, and monitors monkey groups released on islands in areas of known historical occurrence.

In August 2009, a group *S. libidinosus* consisting of 13 individuals (8 males and 5 females) was released and monitored for three consecutive months, for 24 days (eight days per month), totaling 144 h of sampling effort, and over 5 h of effective group observations and data collection. The follow-up protocol includes direct animal focal-scan sampling, recording the animals' foraging and use of space at one-minute intervals. During these observations, predation on eggs and hatchlings of turtles by capuchin monkeys was recorded. Turtle remains were collected and subsequently identified by experts at the Laboratory of Animal Ecophysiology, Department of Systematics and Ecology of the Universidade Federal da Paraíba.

Three events of predation on eggs and young of *Phrynops tuberosus* were observed on 20 September 2009 (approximately 1300 h local time) and two events were noted on 23 October 2009 (at 1211 h and another about 1243 h). This results in a frequency of one predation event / observation hour. In addition, predation traces such as eggshells and damaged turtle shells near the sites of oviposition (Fig. 1) were noted. Although not quantified, qualitative analyses indicate that such events have increased in number over the course of several months. It is noteworthy that no other predator on the island was observed predating turtle eggs or turtles, which reinforces the suggestion that the reintroduced capuchins predated the turtles and their eggs.

FIG. 1. A–B) Brown Capuchin Monkeys (*Sapajus libidinosus*) foraging on the ground. C–D) Eggshells and a broken shell of a young turtle (*Phrynops tuberosus*) found nearby.

Predation on nests and hatchlings of *Phrynops hilarii* and *P. geoffroanus* has been reported (Schneider et al. 2011. Chelon. Conserv. Biol. 10:206–212). However, to date there are no records of predation on turtles in the semiarid caatinga habitat, and this is apparently the first report on predation of *P. tuberosus* nests by the capuchin monkey, *Sapajus libidinosus*.

This report suggests the need for additional studies to measure the impact of reintroduced capuchin monkeys on the population of *P. tuberosus*, as well as on populations of other turtle species that inhabit the release areas. We are grateful to Brazilian Wildlife Rescue Center (CETAS) at Paraíba, Brazil, for logistical support.

***RHINOCLEMMYS RUBIDA PERIXANTHA* (Colima Wood Turtle). COURTSHIP AND MATING BEHAVIOR.** *Rhinoclemmys rubida perixantha* is a small terrestrial turtle endemic to the tropical deciduous forests of western Mexico, ranging from the states of Jalisco to Michoacán (van Dijk et al. 2007. *In* IUCN 2013. IUCN Red List of Threatened Species. Version 2013.1). No information is available on courtship and mating behavior of *R. rubida* in the wild, however courtship in captive animals has been described for its southern relative *R. r. rubida*, housed at the Behler Chelonian Center, where males are aggressive during courtship, following females in circles while biting the forelimbs, displaying rapid head bobbing (both sexes), and rubbing the head and nostrils of the female (Liu 2012. The Tortoise Magazine 1[1]:59). Here I present the first observations of courtship and mating behavior in wild *R. r. perixantha* in its tropical deciduous forest habitat.

On 10 August 2015 at 1255 h, during the wet season in the lowland tropical deciduous forest of the Chamela-Cuixmala Biosphere Reserve (19.49868°N, 105.04449°W; WGS 84) in Jalisco, Mexico, while monitoring six adult male and six adult female *R. r. perixantha* using radiotelemetry, I observed a male (radio tagged) and female *R. r. perixantha* displaying mating behavior on a flat hilltop in upland deciduous forest. As I approached, both male and female were vigorously bobbing heads while rubbing heads and nostrils; shortly after, the male mounted the female twice, but mating was unsuccessful. After the second mount, both turtles retreated to a nearby tree shelter with the male following the female. Partial video of this behavior was captured and is available for review (http://dx.doi.org/10.6084/m9.figshare.1510910). Prior to this observation, from 29 June to 6 August 2015, turtle pairs (male and female together) were seen on hillsides in upland deciduous forest a total of 21 times with males observed behind females, inactive or following. For six of these observations the same male and female were seen together for a second or third time, however, mating behavior was not observed.

Three phases of courtship and mating behavior have been described in *Rhinoclemmys pulcherimma incisa* (Hidalgo 1982. Trans. Kansas Acad. Sci. 85:82–95). In phase one, the male approaches the female, while vibrating his head and neck; in phase two the female engages the male with nose-to-nose contact and biting, presumably signaling to the male to mount; in phase three, the male mounts the female, grasps her carapace, inserts his penis, and performs pumping motions during coition (Hidalgo 1982, *op. cit.*). If courtship and mating behavior rituals are similar in *R. r. perixantha*, the turtle pair observations most likely correspond to phase one; however, six observations of the same pair of turtles several days apart suggests that this phase may last several days. Furthermore, the observation of mating behavior most likely corresponds to phase two, with the female responding, and the beginning of phase three with the male attempting to mount the female. However, phase three may have been disrupted by my presence, as the pair retreated to a shelter shortly after my arrival.

These observations suggest that courtship may take place over several days, and courtship and mating behavior may be similar for other species of *Rhinoclemmys*. Because this species is considered near threatened (van Dijk 2007, *op. cit.*), future research should focus on habitat requirements for turtle reproduction, which may provide insight on critical habitats that should be protected.

I acknowledge Caleb L. Loughran for revision of this note and continued fruitful and informative conversations on herpetofauna. I also thank Daniel Beck for his moral and logistical support on my excursions to the tropical dry forest of western Mexico.

TAGGERT G. BUTTERFIELD, Department of Biological Sciences, Central Washington University, Ellensburg, Washington 98926, USA; e-mail: butterft@cwu.edu.

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle). PREDATION.** Birds and fish can be important predators of small aquatic turtles, but direct observations may be sparse for some species. This note documents both as predators of the Eastern Musk Turtle.

The remains of an immature *Sternotherus odoratus* (CL 53 mm, PL 39 mm; NPS-SEAC-243.1.1) were recovered from a Channel Catfish (*Ictalurus punctatus*; 2.48 kg, standard length 54 cm, total length 60 cm; NPS-SEAC-190.2.1) collected 16 January 2001 in the St. Johns River, between lakes Harney and Jessup, Seminole County, Florida (28.8263°N, 81.1165°W; WGS 84).

During May 1999 and April–May 2000, staff of a local environmental education center in southern Tallahassee, Leon County, Florida, retrieved shells of a series of *S. odoratus* that were dropped from a Red-shouldered Hawk (*Buteo lineatus*) nest (30.4102°N, 84.3442°W) located 100 m and 125 m from two drying depressions at the edge of Lake Bradford (75 m further, also receding). Ten shells (UF 175575–175584) measured 33.9–83.5 mm CL and 23.6–55.4 mm PL and included small juveniles to relatively large adults; the shell of one female still contained the eggshell of an unlaid egg. At least two additional shells were not retrieved. Similarly depredated shells were observed but not collected in 1997 and 1998. These years were marked by substantial drought, which may have stranded turtles in small, shallow pools, leaving them more susceptible to predation than normal.

Feeding upon post-hatchling non-marine turtles has now been documented for several species of North American predatory birds, often in association with feeding nestlings. Such data exist chiefly for Bald Eagles (*Haliaeetus leucocephalus*), which are known to prey upon *Chrysemys picta* (Wood and Smith 2012. Tenth Ann. Symp. Cons. Biol. Tortoises and Freshwater Turtles: 64), *Clemmys guttata* (Clark 1982. J. Field Ornithol. 53:49–51), *Graptemys barbouri* (Means and Harvey 1999. Florida Field Nat. 27:1), *Malaclemys terrapin* (Clark, *op. cit.*; Wood and Smith, *op. cit.*), *Pseudemys nelsoni* (McEwan 1977. M.S. thesis, Univ. Florida), *Terrapene carolina* (Clark, *op. cit.*), *Kinosternon subrubrum* (Clark, *op. cit.*), *Sternotherus carinatus* (Shively et al. 2011. Herpetol. Rev. 42:423), *S. odoratus* (Clark, *op. cit.*; Wood and Smith, *op. cit.*), *Chelydra serpentina* (Clark, *op. cit.*; Wood and Smith, *op. cit.*), *Apalone ferox* (Pike 2005. Herpetol. Rev. 36:440), and *A. mutica* and *A. spinifera* (Watermolen 2004. Bull. Chicago Herpetol. Soc. 39:69–70; Shively et al., *op. cit.*). Additional reports exist for Red-tailed Hawks, *Buteo jamaicensis* (*Gopherus polyphemus*: Fitzpatrick and Woolfenden 1978. Florida Field Nat. 6:49); Red-shouldered Hawks, *B. lineatus* (*C. picta*: Welch 1987. Passenger Pigeon 49:81–92; *S. odoratus*: Kimmel and Fredrickson 1981. Trans. Missouri Acad. Sci. 15:21–27; *Ch. serpentina*: Stewart 1949. Wilson Bull. 61:26–35); Northern Harriers, *Circus cyaneus* (*K. picta*: Bowne 2002. Herpetol. Rev. 33:132); Snail Kites, *Rostrhamus sociabilis* (*S. odoratus*, *K. baurii*, *A. ferox*, *Pseudemys floridana*, *P. nelsoni*: Beissinger 1990. The Auk 107:327–333); Ospreys, *Pandion haliaetus* (*C. picta*: Postupalski and Kleiman 1965. Wilson Bull. 77:401–402; *P. nelsoni*: Wiley and Lohrer 1973. Wilson Bull. 85:468–470); Gulls, *Larus* sp. (*M. terrapin*: Watkins-Colwell 1997. Herpetol. Rev. 28:87–88); American Crows, *Corvus*

brachyrhynchos (*C. picta*: Baxter-Gilbert et al. 2013. Herpetol. Rev. 44:302–303); and Common Ravens, *Corvus corax* (*C. picta*: Baxter-Gilbert et al., op. cit.; *Gopherus agassizii*: Boarman 2002. U.S. Geol. Surv., West. Ecol. Res. Center, Tech. Rpt). In at least one instance, a *K. subrubrum* was able to avoid predation by a raptor (Bald Eagle) by closing its shell tightly (Mitchell et al. 2006. Herpetol. Rev. 37:216–217). However, this option is unavailable to *Sternotherus* and leaves it vulnerable to predatory birds, as shown above.

Coupled with observations from another recent study (Walsh and Heinrich 2015. Florida Field Nat. 43:79–85), these combined observations confirm that, rather than being isolated incidents, avian predation is a regular source of mortality for non-hatchling aquatic turtles. Although fewer data are available, the same may be true for terrestrial turtles.

I thank staff of the Tallahassee Museum of History and Natural Science for monitoring the hawk nest and retrieving turtle remains, and Mike Russo of the National Park Service for lending the specimen from the catfish.

DALE R. JACKSON, Florida Natural Areas Inventory, Florida State University, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA (e-mail: drjackson@admin.fsu.edu).

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle) and *CHRYSEMYS PICTA* (Painted Turtle). INTERSPECIFIC BASKING.** Aerial basking is generally uncommon in *Sternotherus odoratus* (Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed. Johns Hopkins University Press, Baltimore, Maryland. 827 pp.; but see Nickerson 2000. Herpetol. Rev. 31:238–239). Conversely, *Chrysemys picta* are frequent aerial baskers and are often observed basking with conspecifics and occasionally other turtle species (Ernst and Lovich 2009, *op. cit.*). On 30 May 2015 at 1130 h, we observed an adult *S. odoratus* and adult *C. picta* basking in close proximity (ca. 15–20 cm apart) on a log protruding from a canal remnant in the Blue Marsh National Recreation Area, Berks County, Pennsylvania, USA (40.380000°N, 76.031389°W; WGS 84). Both turtles remained on the log and in the same positions during approximately 20 minutes of observation. Although *C. picta* have been noted to display aggressive behaviors (e.g., open-mouthed gestures, biting, and pushing) towards basking conspecifics and other turtle species (Lovich 1988. Herpetologica 44:197–202), we observed no interaction occur between either individual. To our knowledge, interspecific basking has not previously been reported with *S. odoratus* and *C. picta*. Additionally, our observation suggest these species are tolerant toward one another in shared basking locations.

SEAN M. HARTZELL, Department of Biological and Allied Health Sciences, Bloomsburg University of Pennsylvania, Bloomsburg, Pennsylvania 17815, USA (e-mail: smh14844@huskies.bloomu.edu); **JONATHAN E. HARRIS**, 1400 Ridge Avenue, Reading, Pennsylvania 19607, USA; **NEVIN J. RAUP**, 721 2nd Street, Williamsport, Pennsylvania 17701, USA.

***TERRAPENE CAROLINA* (Eastern Box Turtle). COLOR AND PATTERN.** Coloration and pattern of *Terrapene carolina* is highly variable, both in shell and skin (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington DC. 578 pp.; Dodd 2001. North American Box Turtles. A Natural History. University of Oklahoma Press, Norman. 231 pp.). The carapace is typically brownish in ground color with yellow or orange radiating lines, spots, bars, or blotches, and the limbs are usually dark with yellow, orange, or red spots and streaks. Only the plastron is often without pattern, but that too is highly variable (Ernst et al. 1994, *op. cit.*; Dodd 2001, *op. cit.*). On 18 June 2015, a most unusual *T. carolina* (Fig. 1) was observed attempting to excavate a nest in the gravel roadside of McCollum Road, Cherokee Co., Georgia, USA (34.203468°N, 84.492845°W; WGS 84). The individual, an adult female (ca. 130 mm CL), was nearly solid dark brown-black in shell and skin coloration, completely lacking pattern on the carapace, plastron, limbs, and neck. The only noticeable pigmented pattern was a single, small orange spot immediately posterior to each tympanum. Several small, light spots on the carapace represented chips in the epidermal scutes, revealing the lighter bone below rather than actual pigment. I am unaware of any previously published observations of *T. carolina* almost entirely lacking pattern, and in a thorough review of melanism in North American emydids, Lovich et al. (1990. *In* Gibbons [ed.], Life History and Ecology of the Slider Turtle, pp. 233–254. Smithsonian Institution Press, Washington, DC) included no records of this development in *T. carolina*. It seems likely, however, that this individual has displayed this color and lack of pattern its entire life, rather than having become melanistic through ontogeny.

PHOTOS BY JIM BUSCHUR

FIG. 1. Eastern Box Turtle *(Terrapene carolina)* lacking pigmented pattern, with the exception of a single, small orange spot behind the tympanum. Light spots visible on carapace are chips from the epidermal scutes exposing underlying bone.

I thank Brian Folt for reviewing and improving this note.

***TERRAPENE CAROLINA CAROLINA* (Eastern Box Turtle). HIBERNATION SITE FIDELITY.** Hibernation site fidelity has been reported for *Terrapene c. carolina* on several occasions and in several geographic locations but has not been reported for the state of Tennessee. Ernst and Lovich (2009. Turtles of the United States and Canada. Johns Hopkins University Press, Baltimore, Maryland. 827 pp.) reviewed research suggesting that Eastern Box Turtles return to the same overwintering area across subsequent years. Stickel (1989. J. Herpetol. 23:40–44) found that four *T. c. carolina* in Maryland returned to the general area (within several meters) where they had hibernated during previous winters, but the years in which they returned were not always consecutive. Another study done in Maryland found that two individual *T. c. carolina* showed hibernation site fidelity, returning to the same general area across two consecutive winters (Savva et al. 2010. Can. J. Zool. 88:1086–1094). Similarly, Seibert and Belzer (2015. IRCF Reptiles and Amphibians 22:56–67) reported hibernation site fidelity in *T. c. carolina* introduced into a nature sanctuary in Pennsylvania with at least one individual returning to the exact same hibernation site across two winters. In Ohio, one of three monitored *T. c. carolina* hibernated in the exact same location during two winters (1986–1987 and 1988–1989) with one winter in between (1987–1988) in which it overwintered only 8 m away from the original hibernaculum (Claussen et al. 1991. J. Herpetol. 25:334–341).

Three Eastern Box Turtles were fitted with radio transmitters during the active season of 2013 at Nickajack Wetlands and Black Fox Trace (Nickajack) in Murfreesboro, Tennessee, USA. These turtles were tracked throughout the active season and hibernation period. All hibernacula were marked and monitored throughout the winter until emergence in early April 2014. In the winter of 2014, the hibernacula were reexamined for the presence of turtles. One of the three turtles returned to her exact same hibernaculum (35.800017°N, 86.351117°W; WGS 84) and overwintered there until April 2015.

Selection of the hibernation site is very important for box turtles, leading them to return to successful overwintering sites over multiple years (Dodd 2001. North American Box Turtles: A Natural History. University of Oklahoma Press, Norman, Oklahoma. 231 pp.). However, use of the exact same hibernaculum has been reported only a few times, and hibernation site fidelity has never been reported for Eastern Box Turtles in the state of Tennessee. Currylow (2013. J. Wildl. Manage. 77:326–335) suggests that habitat alteration, such as clear cutting, may impact selection of hibernation sites. Further monitoring is important to see how often this phenomenon occurs and to encourage preservation of ideal hibernation sites that are reused year after year.

CROCODYLIA — CROCODILIANS

***ALLIGATOR MISSISSIPPIENSIS* (American Alligator). NESTING BY A REINTRODUCED FEMALE.** The state of Louisiana has an alligator management program that includes a commercial alligator farming program (Elsey and Kinler 2004. *In* Crocodiles. Proceedings of the 17th Working Meeting Crocodile Specialist Group, pp. 92–101. IUCN–The World Conservation Union, Gland, Switzerland and Cambridge UK; Elsey 2013. Herpetol. Rev. 44:309–310). The alligator farming program allows for the collection of eggs from the wild, with mandatory release of a portion of juvenile alligators hatched from collected eggs as a "head-start" program to ensure future recruitment (Elsey and Kinler 2011. *In* Global Re-introduction Perspectives: 2011. More Case Studies from around the Globe, pp. 125–129. Gland, Switzerland: IUCN/SSC Re-introduction Specialist Group and Abu Dhabi, UAE: Environment Agency-Abu Dhabi; Elsey 2013, *op. cit.*). The juvenile alligators released from farms are measured, the sex is determined and recorded, and they are marked with monel tags placed between the toes of the hind legs and by tail notching (Elsey and Kinler 2011, *op. cit.*). The juvenile alligators (allowable size range of 91.4–152.4 cm total length [TL] at release) are then released back to the wetlands from which the eggs were collected one or two years earlier (Elsey 2013, *op. cit.*).

An important measure of the success of this program would be documentation of successful reproduction by the reintroduced alligators after release to the wild. We have observed that many of the released juveniles grow to adult size and are subsequently caught in the annual regulated harvest. We documented presumptive morphological evidence that numerous harvested females had reproductive tracts suggesting they had attained sexual maturity and had ovulated (Elsey et al. 2001. *In* Grigg et al. [eds.], Crocodilian Biology and Evolution, pp. 244–255. Surrey Beatty & Sons Pty Ltd, Chipping Norton, NSW). We have also had numerous reports by commercial egg ranchers of sightings of tail-notched alligators defending nests, yet still lack certain confirmation of fertile eggs being deposited by reintroduced alligators. We have previously reported that in the farm-released alligators, nesting can occur earlier and at a younger age and smaller size than native wild specimens (Elsey et al. 2001, *op. cit.*; Elsey 2007. Herpetol. Bull. 102:11–14). We herein present evidence that a farm-released female alligator nested in the wild, and produced fertile eggs, some of which hatched successfully after collection and incubation.

On 28 June 2014 at approximately 0740 h, CW and an associate were collecting alligator eggs on private wetlands in St. Mary Parish, Louisiana via airboat. As a nest was approached, the female alligator was seen on top of the nest. The airboat operator (CW) attempted to abort the approach to the nest so as to not disturb what appeared to be the female possibly in the process of egg deposition; however airboats are not equipped with brakes, and the boat slid toward the nest due to high water conditions. With the boat now adjacent to the nest, the female was closely observed depositing eggs into the nest cavity. Immediately the female alligator was noted to have tail notches, a method of permanently marking the alligator and indicating it had been released to the wild from a farm as described above. During some twenty minutes of observation, approximately 6–8 eggs were deposited. A series of photographs (Fig. 1) and a video clip were taken; providing clear evidence the farm-released female successfully nested. Tail notches present indicated the female had been released from a farm as part of the "head start" reintroduction program, and the year-specific notches appeared to be those used in 1994. All 32 eggs present (the entire clutch) were collected for incubation at a commercial alligator farm.

Although that specific clutch of eggs was not "flagged" for later identification after incubation, we were later able to review

FIG. 1. Female American Alligator depositing eggs into nest on 28 June 2014 in St. Mary Parish, Louisiana, USA. Year-specific permanent tail notches indicated the female was released to the wild in 1994. Video clip of female depositing eggs also available.

egg hatch records from the alligator farm when egg hatching was completed. Only five clutches were collected that day having a clutch size of 32 eggs, and between 24 and 27 eggs hatched in clutches collected that day wherein 32 eggs were incubated. Thus, we were able to document successful hatching (75.0–84.4%) from eggs laid by a farm-raised alligator after release to the wild.

The tail notch indicated the female alligator was released in 1994; thus she was probably 21–22 years old during the 2014 nesting season (alligators released for the "head-start" program must be released within two years of egg collections; Elsey et al. 2001, *op. cit.*). Some alligators occasionally nest in sequential years, and we have some data available on inter-nest interval (Elsey et al. 2008. Southeast. Nat. 7:737–743). Almost certainly the female alligator observed would have nested several times in the twenty years between release in 1994 and the 2014 observation. This lends further support to the conservation benefits of the egg ranching program in Louisiana as this female likely contributed numerous clutches of hatchlings for population recruitment over the years since initial release to the wild.

As previously reported (Elsey et al. 2001, *op. cit.*) it would be advantageous to have additional data as to nest success and egg viability (clutch size, fertility rates, hatch rates, and hatchling survival) of eggs produced by alligators released from farms. Documentation of a farm-released alligator having survived some twenty years and nesting successfully (and presumably having contributed numerous clutches of eggs over that time interval, adding to population sustainability) lends support to the philosophy of sustained use management of this valuable resource. Other species of crocodilians (including *Crocodylus porosus, C. palustris, C. intermedius*, and *Caiman latirostris*) have been studied for evidence of nesting after release to the wild (see references in Elsey et al. 2001, *op. cit.*). Further information may help refine management programs with reintroductions of crocodilians of other species as well.

***CROCODYLUS ACUTUS* (American Crocodile). LONG DISTANCE JUVENILE MOVEMENT.** *Crocodylus acutus* is the most widely distributed New World crocodilian species with its range extending from Peru in the south to the southern tip of peninsular Florida in the north. *Crocodylus acutus* occupies primarily coastal brackish water habitat, however, it also occurs in freshwater to hypersaline habitats (Thorbjarnarson 2010. *In* S. C. Manolis and C. Stevenson [eds.], Crocodiles. Status Survey and Conservation Action Plan [3rd ed.], pp. 46–53. Crocodile Specialist Group, Darwin). There is limited literature on long-distance movements of juvenile crocodilians worldwide and no literature on juvenile crocodiles in Florida. However, adult *C. acutus* in Florida have been documented to make seasonal movements of 5–15 km from preferred foraging habitat to nesting beaches (Mazzotti 1983. The Ecology of *Crocodylus acutus* in Florida. PhD Dissertation. The Pennsylvania State University, University Park, Pennsylvania. 161 pp.), and one adult was documented making a 35-km trip from her nest site to preferred foraging habitat (Cherkiss et. al. 2006. Herpetol. Rev. 38:72–73). Rodda (1984. Herpetologica 40:444–451) reported on juvenile *C. acutus* movement in Gatun Lake, Panama, and found that juveniles stayed within 1 km of their nest site for the first month. Movements of juvenile *Crocodylus porosus* (Saltwater Crocodile) in a river system in Northern Australia showed a maximum movement of 38.9 km from a known nest site, with the majority of the crocodiles staying within 15.6 km downstream to 6.8 km upstream (Webb and Messel 1978. Aust. Wildl. Res. 5:263–283). Juvenile movement of *Crocodylus niloticus* (Nile Crocodile) in Lake Ngezi, Zimbabwe showed crocodiles restricted their movements from 1.0 km up to

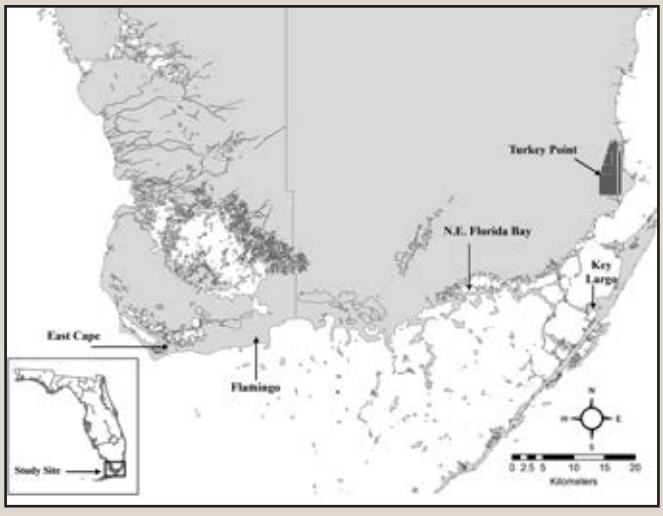

FIG.1 Capture locations for juvenile *Crocodylus acutus* in Florida.

TABLE 1. Initial capture and recapture total length (TL), days, and distance traveled for *Crocodylus acutus* in Florida.

Clip#	Initial / Recapture TL (cm)	Initial Capture Location	Final Capture Location	Days Between Captures	Total distance traveled (km)	Distance traveled (m/day)
809	34.2 /102.0	Chapman Field	N.E. Florida Bay	1646	54.3	30
1361	25.8 / 82.6	Flamingo	Turkey Point	900	59.0	70
2499	23.9 / 96.1	Flamingo	N.E. Florida Bay	1327	34.4	30
3910	26.6 / 40.4	N.E. Florida Bay	Turkey Point	295	34.2	120
4838	25.6 / 101.7	East Cape	Turkey Point	1001	76.3	80
6421	26.9 / 65.2	Flamingo	N.E. Florida Bay	569	36.2	60
6662	26.1 / 93.0	East Cape	Key Largo	584	69.6	120

4.5 km through the wet and dry seasons (Hutton 1989. Am. Zool. 29:1033–1049). Long distance movements of alligators were recorded for sizes ranging from 28 cm to 361 cm in a coastal refuge in Louisiana, where the distance traveled ranged from 0.3 km to 90.2 km. The data showed that the smaller alligators moved greater distance than larger ones (Lance et al. 2011. Southeast. Nat. 10:389–398).

An ongoing 30-year mark and recapture study for *Crocodylus acutus* in Florida allowed us to look at long distance movement (> 30 km) of juveniles (< 1.25 m). Of the 446 individual juvenile crocodiles recaptured, only seven animals demonstrated an exceptional movement (> 30 km). Initial and most recent captures as a juvenile were used to analyze distances moved (Fig. 1). These distances were measured linearly between capture locations. Maximum linear distances of 76.3 km and 69.6 km were recorded for animals 4838 and 6662. All crocodiles moved from nesting habitat through potentially optimal nursery habitat prior to reaching their recapture locations. These juvenile long distance movements could be due to larger crocodiles facilitating their dispersal from the nest location (Lance et al. 2011, *op. cit.*). These data (Table 1) support that there is exchange of individuals among the nesting colonies and our ongoing efforts to monitor this threatened species allow us to make observations of how juvenile crocodiles are moving throughout the landscape in an ecosystem currently undergoing restoration.

SQUAMATA — LIZARDS

BASILISCUS BASILISCUS **(Common Basilisk). PREDATION.** *Basiliscus basiliscus* are very common in streams, rivers, or lakes of Neotropical lowlands and are important in trophic interactions, as prey or predators. They are subject to predation by a wide array of vertebrates such as birds, large fishes, some mammals, and other reptiles. Rarely, invertebrates such as large crustaceans also predate basilisks (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. University of Chicago Press, Chicago, Illinois. 934 pp.; Flaherty and Friers 2014. Southeast. Nat. 13:N57–N58). Here we describe a predation event on a young *Basiliscus basiliscus* (SVL ca. 7 cm) by an invertebrate, a sub-adult female scorpion, *Opisthacantus elatus* (Scorpiones: Hemiscorpiidae). The event was at 1025 h on 26 August 2014, on the shore of Perresénico River, Estación Rancho Frío in Parque Nacional Darién, Darién, Panamá (8.0198907°N, 77.730486°W, WGS 84; 111 m elev.). The scorpion was 200 cm above the ground and positioned horizontally inside an interstice of a fallen branch, but with the anterior carapace region and the right pedipalp outside and holding with the chela the posterior left leg of the lizard. The lizard made occasional movements forward to escape but the scorpion held strong. We pulled the lizard with herpetological tongs and the scorpion held stronger. *Opisthacantus elatus* has a considerable mechanical strength to trap and manipulate large prey and is found more frequently under rocks or fallen trunks (Álvarez et al. 2013. Rev. Col. Entomol. 39:301–304). We think that the scorpion climbed up the fallen branch to hide and hunt. However, we did not see the scorpion eat the lizard. We captured both animals; the scorpion was deposited in Museo de Invertebrados de la Universidad de Panamá (MIUP) with collection data, but the lizard escaped after capture. Other lizards in the genera *Homonota*, *Podarcis*, *Liolaemus*, and some geckos have been preyed upon by scorpions (Fulvio and Minoli 2014. Cuad. Herpetol. 28:1–2). This is the first observation of a large scorpion trapping young *B. basiliscus*, presumably for predation, and gives insights to consider *O. elatus* as ecological pressure for young basilisks.

We thank Fondo Darién for financial support, Ministerio de Ambiente de Panamá for logistical facilities in Parque Nacional Darién, and Diomedes Quintero from MIUP for identification of the scorpion and determination of the sex.

LUIS ELIZONDO, Programa de Maestría en Ciencias Biológicas, Vicerectoría de Investigación y Postgrado, Universidad de Panamá, Avenida Simón Bolívar (Carretera Transístmica), Ciudad de Panamá, Panamá; Apartado 3366 Panamá 4, Panamá (e-mail: elizondolui@gmail.com); **MAYKELL MORALES** and **SEAN ROMAÑA**, Escuela de Biología, Universidad de Panamá, Avenida Simón Bolívar (Carretera Transístmica), Ciudad de Panamá.

BRASILISCINCUS HEATHI **(Brazilian Mabuya). TAIL BIFURCATION.** Tail bifurcation has been commonly reported for several lizard families worldwide such as Agamidae (Ananjeva and Danov 1991. Amphibia-Reptilia 12:343–356), Diploglossidae (Cozendey et al. 2013. Herpetol. Rev. 44:145–146), Scincidae (e.g., McKelvy and Stark 2012. Herpetol. Rev. 43:138; Mitchell et al. 2012. Herpetol. Rev. 43:650), Teidae (Gogliath et al. 2012. Herpetol. Rev. 43:129), and Tropiduridae (Martins et al. 2013. Herpetol. Notes. 41: 369:371), including bizarre cases of species exhibiting from three to six regenerated tails (Koleska and Jablonski 2015. Ecol. Mont. 3: 26–28; Pelegrin and Leão 2015. Cuad. Herpetol. 30:1–3). Most tail bifurcation observations were reported for a single individual and usually found at low rates within populations (Vrcibradic and Niemeyer 2013. Herpetol. Rev. 44:510–511).

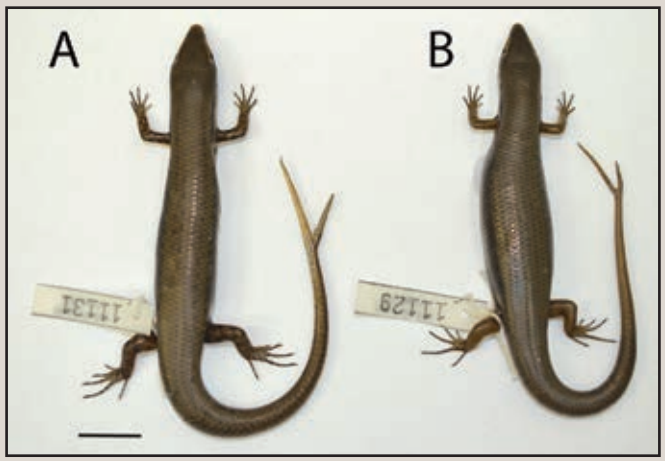

FIG. 1. A) Adult male (AAGARDA 11131), and B) pregnant female (AAGARDA 11129) *Brasiliscincus heathi* exhibiting tail bifurcation. Scale = 10 mm.

Herein, we report the first case of tail bifurcation in multiple individuals within a population of the Neotropical skink *Brasiliscincus heathi*.

During a field survey at Serra das Confusões, Piauí State, Brazil (9.1410°S, 43.5619°W, WSG84; 510 m elev.) in October 2014 we collected two adult *Brasiliscincus heathi* with tail bifurcation from an area of rock outcrops. The first individual, a male (AAGARDA 11131; SVL = 69.8 mm, Fig. 1A) had 22.5 mm of original tail followed by a regenerated portion extending to 47.8 mm before bifurcating into a smaller (8.6 mm) lateral and a larger (15.9 mm) axial branch. The second individual, a pregnant female (AAGARDA 11129; SVL = 64.7 mm, Fig. 1B) had an original (non-regenerated) portion of tail 41 mm long, followed by a regenerated portion extending 29 mm before bifurcating into a smaller lateral (6 mm) and a larger (12 mm) axial branch. Along with these two individuals, we collected 12 more specimens from which 8 exhibited a regenerated tail (not including the specimens with bifid tails). In this case, the frequency of bifurcated tail as a consequence of tail regeneration can be estimated as 20% (2/10).

Vrcibradic and Niemeyer (2013, *op. cit.*) provided an estimation of tail bifurcation for populations of *Notomabuya frenata* and *Psychosaura macrorhyncha* (1.7% and 1.2%, respectively). Such estimations were made through the examination of several individuals (more than 100 specimens) from each species. Although we examined fewer individuals, the elevated frequency found by us (20%) might indicate that this abnormality occurs at a high rate within our studied population or such estimation may be biased due to an insufficient sampling. Nevertheless, this abnormality does not seem to affect the fitness or survival rate of the individuals as a pregnant female was found exhibiting a bifid tail.

We are grateful to Adrian Antonio Garda for suggestions. Collections were made under permit (SISBIO # 46129-1).

***CALOTES VERSICOLOR* (Oriental Garden Lizard). DIET.** *Calotes versicolor* is among the most geographically widespread members of the genus (Uetz and Hošek 2014. The Reptile Database. http://reptile-database.reptarium.cz, accessed 29 Apr 2014) naturally occurring in Afghanistan, Bangladesh, Bhutan, Cambodia, India, Indonesia (Sumatra), Myanmar, Nepal, Pakistan, Peninsular Malaysia, South East Iran, Singapore, South China, Sri Lanka, Thailand, and Vietnam, and additional introduced populations in Sulawesi, Malaysian Borneo, Maldives, Mauritius, Oman, Seychelles, and USA (Florida) (Enge and Krysko 2004. Florida Sci. 67:226–230; Matyot 2004. Phelsuma 12:35–47; Radder 2006. Curr. Sci. 91:1354–1363). It is a very adaptable, prolific species and is commonly found in human-altered environments including highly urbanized areas (Erdelen 1988. J. Herpetol. 22:42–52). Although it is generally considered an insectivore, field records suggest that it is more an opportunistic omnivore with a wide range of prey. However, such records are often scattered in gray literature and in this review we collate published records and observations of our own and those of our colleagues, and subsequently discuss the possible reasons for dietary breadth.

Our review revealed records of *Calotes versicolor* feeding on members of nine broad faunal groups (annelids, mollusks, insects, myriapods, arachnids, crustaceans, amphibians, reptiles, birds, and mammals) as well as plant matter (Table 1). Insects comprise most of the diet of *C. versicolor*. One of us (HS) observed an adult lizard feeding on a swarm of ants on the ground at a rate of one ant in every five to six seconds for ca. 30 seconds. Sit-and-wait foraging patterns have also been used to catch wasps visiting a puddle of water (Supun Wellappuliarachchi, pers. comm.). *Calotes versicolor* even preys upon large species like the Atlas Moth (*Attacus taprobanis*) (HS, pers. obs.). Additionally, orthopterans, mantodeans, dipterans, odonates, blattodeans, hemipterans, and dermapterans constitute a lesser content in the diet (Rao 1975. Brit. J. Herpetol. 5:467–470; Indurkar and Sabnis 1976. Comp. Physiol. Ecol. 1: 9–12; Sharma and Vazirani 1977. Rec. Zool. Surv. India 73:77–93; Chandra 1983. Plant Protection Bulletin 35:35; Qiu et al. 2001. Zool. Res. 22:367–374). Annelids are a constituent of the diet of *C. versicolor*, but are represented in a low volume in gut contents (Rao 1975, *op. cit.*) which could be due to high digestion rate of soft-bodied prey (Verheyen 1991. Funct. Ecol. 5:507–517; Qu et al. 2011. Curr. Zool. 57: 684–700). RS observed an adult male feeding on a small annelid, *Megascolex coeruleus*, that emerged on the surface soon after a rain. This lizard generally forages on the surface (tree trunks or on ground), but can opportunistically unearth fossorial prey like annelids (Sharma 2002. Cobra 48:14–15). RS observed a sub-adult lizard preying on an asparassid *Heteropoda venatoria* and a failed attempt of an adult female to catch a sub-adult theraphosid *Poecilotheria pedersoni* (before it escaped to a tree hollow) in Sri Lanka.

Several groups of herpetofauna, including amphibians, agamids, geckos, skinks, and snakes are known prey items of *C. versicolor*. Records of feeding on juveniles of other agamids are common. S. Wellappuliarachchi (pers. comm.) observed an adult *C. versicolor* preying upon an injured *C. calotes* (SVL ca. 80–100 mm) after the latter was attacked by a cat. Holding its prey by the belly, the lizard hit the *C. calotes* on a brick wall vigorously several times and then carried it onto the top of a coconut tree. Senanayake (1980. Tiger Paper 7:26–28) reported

the Sri Lankan montane agamid *Ceratophora stoddarti* as a prey item of *C. versicolor*. However, currently *Ceratophora stoddarti* and *C. versicolor* are largely allopatric and thus this report seems questionable. Several species of geckos including *Hemidactylus frenatus* (S. Wellappuliarachchi, pers. comm.) and *H. leschenaultii* (RS, pers. obs.) are also taken. Several incidents of these lizards taking small snakes as prey are known from India (Sharma 1998. J. Bombay Nat. Hist. Soc. 96:146–147; Kalaiarasan and Rajarathinam 2005. Cobra 61:16–20; Thite and Nerlekar 2012. Herpetol. Notes 5:518–518). Endotherms are arguably rare in the diet of *C. versicolor*, but they do feed on bird eggs, nestlings, and adult birds (Daniel 1983. The Book of Indian Reptiles. Bombay Natural History Society, Bombay, India; Dhindsa and Toor 1983. J. Bombay Nat. Hist. Soc. 80:221–222; Paralkar 1995. J. Bombay Nat. Hist. Soc. 92:426). S. Wellappuliarachchi (pers. comm.) observed an adult lizard (total length ca. 180–200 mm) feeding on a *Mus* sp. (Field Mouse) in Sri Lanka, taking more than 20 minutes to completely swallow it, during which the lizard frequently squashed the mouse by hitting it on a rock. However, it is uncertain whether the lizard actively caught the live mouse or if the mouse was scavenged.

Plant material is also a known component of the diet. The reason for feeding on plant matter is not clear, but could be for obtaining moisture (Devasahayam and Devasahayam 1989. J. Bombay Nat. Hist. Soc. 86:253) as well as nutrients (Indukar and Sabnis 1976, *op. cit.*), or could reflect secondary or accidental ingestion (Rao 1975, *op. cit.*; Bhatti et al. 1988. J. Bombay Nat. Hist. Soc. 84:692–693). However, active feeding on plant matter has been observed (Sekar 1987. J. Bombay Nat. Hist. Soc. 85:199; Devasahayam and Devasahayam 1989, *op. cit.*; Sharma 1994. J. Bombay Nat. Hist. Soc. 91:150; Sharma 1998. Cobra 34:21–22; Aengals 2000. Cobra 40:18).

Several factors may influence the wide spectrum of food habits known for this species. 1) *Calotes versicolor* is among the most widespread non-gekkonid lizards in the world (Enge and Krysko 2004, *op. cit.*; Matyot 2004, *op. cit.*; Radder 2006, *op. cit.*), thus would encounter and hence could potentially prey on a large range of prey items within its range. 2) It is a relatively large lizard where males may attain 140 mm (SVL) and a total length over 450 mm (Radder et al. 2001. J. Herpetol. 35:156–160). Adults also have large heads with a relatively wide gape. Body size is known to greatly influence many aspects of the morphology, physiology, and ecology of organisms (Meiri 2008. Global Ecol. Biogeog. 17:724–734.), thus prey size as well prey spectrum could vary linearly with the size of the predator allowing them to consume a larger range of prey items. Arguably, this could help them displace populations of smaller competitors (e.g., *Bronchocela cristatella* in Singapore: Diong et al. 1994. Nature Malaysiana 19:46–54). 3) *Calotes versicolor* is commonly observed in anthropogenic habitats including home gardens, parks, plantations, and cities (Somaweera and Somaweera 2009. Lizards of Sri Lanka: A Colour Guide with Field Keys. Chimaira Buchhandelsgesellschaft mbH, Frankfurt am Main. 304 pp.). Individuals often forage on ground, foliage, and on man-made structures, and males often display from fences and other conspicuous perches. Hence the species is more commonly seen, increasing the likelihood of observing foraging behavior. This explains why most feeding observations are anecdotal and opportunistic in man-made environments.

Diet breadth and foraging success are of great importance in understanding the distribution of a predator and to understand its population dynamics and inter-specific interactions (Pitt and Ritchie 2002. Oikos 96:157–163). Coupled with its wide thermal tolerance limits (Qiu et al. 2009. Acta Ecol. Sinica 29:1738–1744) and habitat generalism (Radder 2006, *op. cit.*), a broad diet may have assisted the colonizing success of this species.

We thank I. Agarwal, T. Amarasinghe, B. Dayananda, M. Elphick, S. R. Ganesh, M. Greenlees, M. Gunawardena, S. Karunarathna, B. Kekulandala, K. Maduwage, U. Manthey, Chandra Mouli, N. Perera, G. Vogel, and S. Wellappuliarachchi for providing literature and personal observations.

***CHAMAELEO ZEYLANICUS* (Indian Chameleon). CLUTCH SIZE.** Reported clutch size of *Chamaeleo zeylanicus* ranges from 10–33 (Daniel 2002. The Book of Indian Reptiles and Amphibians. Bombay Natural History Society and Oxford University Press, Mumbai. viii + 238 pp.; Das 2002. A Photographic Guide to Snakes and other Reptiles of India. New Holland Publishers [UK] Ltd, London. 144 pp.). One female *Chamaeleo zeylanicus* (357 mm total length) was confiscated at Kolkata, West Bengal, India by authorities on 1 November 2014 and was housed in the Wildlife Rescue Centre, Kolkata. On 3 November 2014 at ca. 1030 h we found a clutch containing 65 eggs in the enclosure. The eggs were laid in a water bowl and a few eggs were drowned and rotten at the time of collection. Egg diameter ranged from 20–21.2 mm in length (mean: 20.54 mm) and 14.9–15.6 mm in width (mean: 15.32 mm). The top of the eggs were marked with a non-toxic marker during collection to avoid turning of eggs and 60 healthy looking eggs were kept in a plastic container (25 cm × 30 cm × 15 cm) with vermiculite as an artificial substrate for incubation. Small holes were made in the lid for circulation of air. The container was kept inside a wooden cupboard. To maintain temperature, external heat source of a 100-watt bulb was used. The bulb was kept on during the night to keep the ambient temperature between 27–30°C. The eggs were sprayed lightly with water when they looked dry.

By February 2015, 31 eggs were rotten. The rotten eggs were removed when found. On 29 May 2015 at ca. 1130 h, after 207 days of incubation, the first hatchling was observed to put its head out from one of the eggs. When it failed to get out by itself after another two hours, it was manually pushed out of the eggshell.

FIG. 1. Clockwise from upper left: Eggs, emergence, healthy hatchlings, and care of weak hatchling of *Chamaeleo zeylanicus*.

The hatchling started moving within a minute and then opened its eyes. It was shifted to a bigger container (25 cm × 36 cm × 27 cm) and was given twigs to climb on. In the next seven days, 18 more eggs hatched at varying times of the day. On 12 June 2015 ca. 2150 h, after 222 days from the date of laying the final hatchling emerged. Smith (1935. The Fauna of British India, Ceylon and Burma. Reptiles and Amphibia, Vol. II.Sauria. Taylor and Francis, London. 440 pp.) noted the clutch size to be 31 and the egg size to be 13 mm × 7 mm. He also mentioned another clutch containing 13 eggs that measured 19 mm × 12 mm. Another study noted the species has an incubation period of eight months and a clutch size of 32–40 with the range of size and weight of the eggs to be 15–22.5 mm × 9–12 mm and 1–2 g (Singh et al. 1984. J. Bombay Nat. Hist. Soc. 81[1]:86–92). Our present report documents the largest clutch size recorded for the species.

The snout–vent length of the hatchlings ranged from 23–32 mm (mean = 27.6 mm) and the tail length ranged from 31–38mm (mean = 34 mm). Singh et al. (1984, *op. cit.*) reported the size of four hatchlings: total length 70–72.5 mm, SVL 30–34.5. The weight of the hatchlings ranged from 0.93–1.8 g (mean = 1.3 g). The weak embryos which still had good amount of yolk inside their umbellica were carefully transferred to disinfected banana leaves to cushion them and were kept in a separate plastic container at room temperature (ca. 31ºC). They recovered within 24–36 h. Some eggs showed pipping but they failed to emerge. These eggs were carefully slit with a scalpel to assist emergence. The remaining nine eggs were kept under observation for another seven days. Then they were cut open. Five of those eggs had fully formed dead embryos. The remaining eggs did not form any embryos and yolk was in liquid state. Twenty eggs were thus successfully hatched.

We thank Singaram Kulandaivel (Divisional Forest Officer, Wildlife Headquarter, West Bengal), Shankar Dutta (Ranger), Michele Smith, Arjan Basu Roy, Somnath Majhi,

***COLEODACTYLUS MERIDIONALIS* (Meridian Gecko). PREDATION.** The lizards of the genus *Coleodactylus* (Sphaerodactylidae) are widely distributed in northeastern South America (Kluge 1995. Amer. Mus. Novit. 3139:1–23). This genus is composed of a complex of small diurnal species that inhabit leaf litter (Ávila-Pires 1995. Zoologische Verhandelingen 299:1–706; Vanzolini 1968. Arq. Zool. 17:1–84). *Coleodactylus meridionalis* is a litter-dweller distributed in the Caatinga and Atlantic Rainforest of northeastern Brazil (Ribeiro et al. 2013. Herpetol. Notes 6:23–27). Here we report a predation event on an individual of *C. meridionalis* (SVL = 26.18 mm; tail length = 20.84 mm; 0.3 g) by *Brasiliscincus heathi* (SVL = 65.96 mm; tail length = 77.8 mm; 6.1 g). On 18 November 2014 at 1611 h, in Serra Grande (6.503499ºS, 35.933579ºW; WGS 84) municipality of Cuité, Paraíba State, northeastern Brazil, during an active search in leaf litter for reptiles, we observed a *C. meridionalis* being preyed upon by a *B. heathi* (Fig. 1). The observation lasted at least five minutes, after which the lizards were collected and subsequently euthanized, fixed with 10% formalin, and deposited at the Coleção Herpetológica da Universidade Regional do Cariri (URCA-H 10.176 and 10.164, respectively). Although *C. meridionalis* has been reported in the diet of *Tropidurus hygomii* (Vargens et al. 2005. Herpetol. Rev. 36:173–174), to our knowledge this is the first record of predation of *C. meridionalis* by *B. heathi*.

FIG. 1. Predation of *Coleodactylus meridionalis* by a *Brasiliscincus heathi*, Paraíba, Brazil.

***CTENOSAURA OAXACANA* (Oaxacan Spiny-Tailed Iguana). PREDATION.** *Ctenosaura oaxacana* is a critically endangered species distributed in tropical dry forest along the Pacific coast of the Mexican state of Oaxaca (Köhler 2004. IUCN 2013; Köhler and Hasbún 2001. Senckenberg Biol. 81:257–267). As part of an ongoing project to examine *C. oaxacana* habitat use, we radiotracked *C. oaxacana* outfitted with Holohil Ltd. PD-2 transmitters affixed externally at the dorsal base of the tail with the antenna extending anteriorly. On 25 May 2014 and 30 May 2014 in San Pedro Huamelula Municipality, we found one adult female and one adult male radio tagged iguanas (13.5 cm SVL, 20.5 cm tail length, 84 g, and 15.4 cm SVL, 17.5 cm tail length, 107 g, respectively) each ingested by adult female Western Lyre Snakes (*Trimorphodon biscutatus*) (99.8 cm SVL; 18.4 cm tail length; 215 g, and 104.5 cm SVL, 20.5 cm tail length, 292 g, respectively). The *T. biscutatus* were maintained at ambient temperature for 5 and 10 days, respectively, until the transmitter and string attached to iguana scales were defecated (snake mass post-defecation = 175 g and 225 g, respectively). The iguanas represented 48.0% and 47.6% of the snake body mass, and 28.8% and 26.3%, of the total length of the snakes respectively, considering 4 g mass of receiver and glue.

Trimorphodon biscutatus is a mostly terrestrial, nocturnal, active forager known to predate snakes, mammals, and diurnal lizards including *Ctenosaura* (Scott and Norman 1984. Cat. Amer. Amph. Rept. 353.1–353.3). In Costa Rica, *T. biscutatus* is one of the main predators of *C. similis* (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. University of Chicago Press, Chicago, Illinois. 934 pp.). A juvenile *C. pectinata* (30 cm SVL; 46 cm tail length; 405 g) predated by a *T. biscutatus* (150 cm SVL; 25 cm tail length; 1183 g, representing 34.2% of body mass of the snake) proved fatal within 20 minutes of ingestion (Ramírez-Bautista 1992. Herpetol. Rev. 23[3]:82) despite the *C. pectinata* being relatively smaller in size than the *C. oaxacana* predation instances we present here. These observations represent the first reports of *C. oaxacana* being predated by *T. biscutatus* and establish that adults are susceptible to predation by relatively small snakes while in refugia. Our observations also add to the understanding of relative meal size in *T. biscutatus*.

***LIOLAEMUS TENUIS TENUIS* (Slender Jewel Lizard). NOCTURNAL ACTIVITY.** The highly speciose genus *Liolaemus* is widespread in southern South America but only a few species have been described as human commensals in the way that they survive, proliferate, and colonize urban or suburban areas (Vidal and Labra 2008 [eds.], Herpetología de Chile. Science Verlag Ed., Santiago, Chile. 600 pp.). Despite a remarkable diversity of ecological and biological traits, all species are diurnal. This note documents a case of nocturnal activity in *Liolaemus tenuis tenuis*, a small lizard with a wide distribution in central Chile, but in Argentina is only found in a small area covered with Andean-Patagonian forest, in Neuquén Province (Christie and Sage 2002. Cuad. Herpetol. 16:80–82). The present observation occurred after 2200 h on a wall facing northeast on the main building hallway of Hosteria Piedra Pintada (39.1177°S, 71.0967°W, WGS 84; 1046 m elev.) at Provincial Road 11 (km marker 50), on the southern coast of Pulmari Lake, Alumine Department, Neuquén Province. On 24 January 2013, several lizards (4–5) were observed around an illuminated electric wall lantern, situated ~ 2.50 m above ground and surrounded by branches of an ornamental rose vine. Apparently, they were feeding on insects but when we approached to less than 5 m all but one adult female ran away in different directions. This individual was photographed with a digital camera (Fig. 1) and remained in the same position for ~ 2 minutes until she started moving around the lantern and between vegetation to finally disappear from our view after two or three minutes. Three other smaller individuals were later observed moving near the lamp over the next 15–20 minutes but vine foliage density obscured clear spotting and accurate identification. Our observation occurred on an unusually warm night (> 20°C) and after a hot day that probably warmed the building walls allowing lizards to maintain nocturnal activity. This observation is apparently the first report of nocturnal activity in *L. tenuis tenuis* and probably for the entire genus. Other species of *Liolaemus* may remain active for a brief period after nightfall via thigmothermy on warm substrates but this has only observed in desert species (e.g., *L. darwinii*, *L. olongasta*, *L. koslowskyi*) in the Monte biogeographic region but never in colder regions such as the Andean Patagonian forest.

FIG. 1. A) Adult female of *Liolaemus tenuis tenuis*. B) Lantern and wall where nocturnal activity was observed, white arrow marks exact place were female was photographed.

***MENETIA GREYII* (Grey's Skink). DIET.** Despite widespread insectivory there are remarkably few records of the species identity of insect dietary items of any Australian lizard species, and little is known of the biology of the minute terrestrial lygosomine skinks of the genus *Menetia*. On 29 October 1990, 1400 h, MP detected a mature adult (SVL 32 mm) *Menetia greyii* Gray, 1845, with complete original tail eating an adult (total length ca. 25 mm) damselfly, *Austrolestes io* (Selys, 1862) (Odonata: Zygoptera: Lestidae), on brick pavers in the brick wall-enclosed backyard (ca. 7 × 3 m) of Unit 1/12 Hannibal Street, Palmyra, metropolitan Perth, Western Australia, Australia (32.038056°S, 115.780278°E, WGS 84; 20 m elev.). When first observed, the *M. greyii* had already swallowed most of the *A. io*, head-first and including all four wings, and it was only detected by ca. 3 mm of the abdomen protruding from the mouth. The *M. greyii* eventually regurgitated the *A. io* after 5–6 minutes, perhaps because of perceived threat due to close proximity and movements of the photographer and disturbance from the camera flash, but more likely due to the *A. io* being too long for the *M. greyii* to swallow completely, as it spent 2–3 minutes attempting to swallow the rest of the abdomen even after we had stopped taking photos. Neither subject was retained. Observations were made on a sunny mid-spring day with no cloud cover or perceptible wind; temperature was not recorded. The *M. greyii* was one of 4–5 adults resident in the yard, which was void of vegetation except for two exotic succulents 20–30 cm high situated at the base of a wall; small populations of two arboreal species, the larger skink *Cryptoblepharus buchanani* and the gecko *Christinus marmoratus*, were present on brick walls of the building by day and night, respectively.

Austrolestes io would therefore appear to be just beyond the upper size-limit of single prey items for adult *Menetia greyii*, although whether there were other prey items in the gut that may

have impeded full swallowing was undetermined; lizards may occasionally attempt to swallow single prey items beyond their gustatory capacity, and then regurgitate the swallowed portion (e.g., the eublepharid gecko *Coleonyx variegatus* with a large road-killed centipede, Gardner and Mendelson 1999. Herpetol. Rev. 30[4]:227), as likely the case in the above observations. Other lizard species have been occasionally reported to deal with relatively large arthropod prey items by disarticulation and then consumption of the portions (e.g., the polychrotid *Anolis uniformis* with large Alate Diptera, Eifler 1995. Herpetol. Rev. 26[4]:204; the teiid *Ameiva ameiva* with large cerambycid beetles, Morato 2012. Herpetol. Rev. 43[3]:328), however this did not occur in the above case. How this strictly terrestrial species was able to secure the *A. io* in the above interaction is unknown (not observed); this may have been by active predation, or opportunistic salvage of an individual killed or injured by another predator such as a bird or spider.

There is a report of *Menetia greyii* hunting insects in a lump of dry branches in Fromes Creek, 2 km W of Banncannia waterhole, Sturt NP, New South Wales (NSW), arid east Australia, but identities of the potential prey were not provided (Henle 1996. Herpetofauna 26[1]:12–25). Gut content analysis of vouchers from two semi-arid localities in southern Australia (N = 85; most from "Erskine Park," Salter Springs, 85 km N of Adelaide; 13 km from coastal Port Gawler, 30 km N of Adelaide) revealed 128 identifiable remains of various small Arthropoda (most Insecta) as dietary items of 44 *M. greyii*, 45% termites (Isoptera), 13% bugs (Hemiptera), 10% ants (Hymenoptera: Apocrita: Formicidae), 9% beetles (Coleoptera), 8% spiders (Arachnida: Aranea), 7% moths (Lepidoptera), and a few flies (Diptera), cockroaches (Blattodea), nymphal grasshoppers (Orthoptera), and pseudoscorpions (Arachnida: Pseudoscorpiones) (Smyth and Smith 1974. J. Herpetol. 8[4]:329–35). More recently, gut content analysis of a larger sample (N = 448) of *Menetia* "*greyi*" [*sic*] from sites in the Great Victoria Desert in arid west Australia (some collected by the present first author) found 468 dietary items in 146 vouchers, comprising (by conversion of proportions of numbers to percentages) 33.1% spiders (Aranea), 22.2% silverfish (Thysanura), 17.7% bugs (Hemiptera), 3.4% beetles (Coleoptera), 3.4% termites (Isoptera), 2.6% ants (Formicidae), 3.0% mites (Arachnida: Acarina), 2.4% grasshoppers (Orthoptera), 1.5% flies (Diptera), 0.9% (proportion given as .004, in error) wasps (Hymenoptera: Apocrita), 0.9% pseudoscorpions (Pseudoscorpiones), 0.6% cockroaches (Blattodea), 0.2% moths (Lepidoptera), 0.2% centipedes (Myriopoda: Chilopoda), 2.1% other Insecta, 4.7% eggs and 1.3% larvae (presumably Insecta), 0.2% unidentified plant remains, and 0.1% unidentified (Pianka 2011. West. Austral. Nat. 28[1]:12–17). Other than ants (resolvable to family), no identities of prey items to species, genus, or family were given in these papers. Both studies found diets comprised of small arthropods, but the range of arthropod orders taken and proportions in diets differed markedly. Most striking, Isoptera were the dominant item in diets in the southern Australia sample, but comprised a low proportion of items in the west Australia sample which instead was dominated by Aranea and Thysanura with the latter dominant by volume (35.3%) but absent in the southern Australia sample; discrepancy in the results of gut content analyses illustrates how diets in the same species may vary between different regions and habitats, and perhaps with year and season. A notable feature in both studies was the apparent absence of prey items in a large proportion of vouchers (ca. 67.41% and 48.24%, respectively). All prey items in both studies were of small size, relative to their predators, however our above record indicates that the range of prey-size taken by *M. greyii* is much greater than previously reported, and may include items of roughly equivalent body length to themselves in diets; although protagonists were not weighed, the mass of the single item would have constituted a major proportion of unfed total body mass of the predator in this interaction. Our record is also notable as the first report of predation by *M. greyii* on Odonata.

Menetia greyii is distributed over most of the Australian mainland except much of Victoria, the southeast coast, the eastern slopes of the Great Dividing Range, and Cape York (Cogger 2014. Reptiles and Amphibians of Australia [7th ed.]. CSIRO Publishing, Collingwood, Victoria, Australia. xxx + 1033 pp.), with apparently isolated populations in the northern Australian Capital Territory (ACT) (Jenkins and Bartell 1980. A Field Guide to Reptiles of the Australian High Country. Inkata Press Proprietary Limited, Melbourne. 2 pp. [unpaginated] + 278 pp.) and the Northern Tablelands of NSW (DCM, unpubl. data); as currently conceived *M. greyii* includes both sexual and parthenogenetic populations. *Austrolestes io* is a disjunctly distributed southern Australian species, present in Tasmania, Victoria, southern ACT, and in the southwest of Western Australia where it is relatively common, but is infrequently encountered and therefore likely sparsely distributed in southeastern Australia (MP, unpubl. data). The current known distributions of the predator and prey species in the above interaction only overlap in southwest Australia with the isolated population of the latter, although known localities of the two species approach in the highlands of the ACT.

We thank Brenda Coulson for assistance in observations.

MAGNUS PETERSON, Unit 5/33 Point Walter Rd., Bicton, WA, Australia 6157; **DEAN C. METCALFE**, PO Box 4056, Werrington, NSW, Australia 2747 (e-mail: dean_metcalfe@yahoo.com.au).

***MICROLOPHUS BIVITTATUS* (Lava Lizard). PREDATION.** On 13 January 2015 at 1138 h we observed an *Ardea alba* (Great Egret) stalk, capture, and consume an adult female *Microlophus bivittatus* in Puerto Baquerizo Moreno, San Cristóbal, Galápagos, Ecuador (0.90336°S, 89.6105°W). The setting was an urban vacant lot with scattered building material and low plants. *M. bivittatus* were conspicuously common in the town, and appeared to be the only available food there for *A. alba*; the close flight distance of *A. alba* in the Galápagos probably contributed to its ability to forage in a busy urban area. *Ardea alba* normally forage in nearshore habitats and are native to San Cristóbal (Fitter et al 2000. Wildlife of the Galápagos, Princeton University Press, Princeton, New Jersey. 254 pp.). The capture and consumption took approximately 20 seconds.

***OPLURUS CUVIERI CUVIERI* (Madagascan Spiny-tailed Iguana). DIET.** Several studies have shown that *Oplurus cuvieri cuvieri* mainly prey on invertebrates, with a high proportion of those being ants, and also occasionally feeds on plant materials (Delheusy and Bels 1992. J. Exp. Biol. 170:155–186; Randriamahazo and Mori 2012. Curr. Herpetol. 31:8–13). In addition, two reports suggest active predation on nestling birds by *O. c. cuvieri*. Eguchi (2005. *In* Yamagishi [ed.], Social Organization of the Rufous Vanga, pp. 83–104. Kyoto Univ. Press, Kyoto, Japan) observed that

FIG. 1. *Oplurus cuvieri cuvieri* climbed the tree while holding adult *Cinnyris sovimanga*.

an adult *Schetba rufa* (Rufous Vanga) intensively attacked an individual of *O. c. cuvieri* that came close to a nest of the *S. rufa*, and he inferred that *O. c. cuvieri* feeds on nestlings of *S. rufa*. Ito (2013. Herpetol. Rev. 44:678) reported a predation event of *O. c. cuvieri* on a fledgling of *Hypsipetes madagascariensis* (Madagascar Bulbul) that had fallen from its nest. Here, we report a case of active predation on an adult bird by *O. c. cuvieri*.

In Ampijoroa forest of Ankarafantsika National Park, Madagascar, at approximately 1150 h on 2 December 2012, we found a pair of *Cinnyris sovimanga* (Souimanga Sunbird) perching on a branch of a tree approximately 4 m high. An adult male *Oplurus cuvieri cuvieri* (SVL ca. 170 mm) approached the base of the tree and started to climb the trunk. The lizard intermittently climbed up to an approximately 3-m high branch in several minutes. At the branch, the lizard turned toward the birds and slowly came close to them. Then the lizard stepped on another branch and remained motionless for approximately 10 seconds at this position 20 cm behind the birds. At 1205 h, the lizard sprang at the male *C. sovimanga* from the branch and held the bird with its mouth. Although they fell down to the ground together from the branch, the lizard was still holding the bird with its mouth. Immediately after the landing, the lizard ran away to another tree approximately 5 m away and quickly climbed the tree while holding the bird (Fig. 1). Finally, the lizard began to eat the bird on a branch 4 m high. This is the first report on active hunting of adult birds by *O. c. cuvieri*.

This study was financially supported by JSPS Grant-in-Aid for Scientific Research (B: no. 24405008). We thank Akira Mori for his valuable suggestions and staff of Madagascar National Park for their assistance in the field study.

***PHRYNOSOMA CORNUTUM* (Texas Horned Lizard). HABITAT USE.** The combination of high temperatures and low humidity from lack of precipitation, as has happened frequently over the last few years in Oklahoma, USA, can create desiccation cracks in dry, bare clay soil (Morris et al. 1992. Can. Geotech. J. 29:263–277; Peron et al. 2009. Can. Geotech. J. 46:1177–1201; Burmeier et al. 2010. Plant and Soil 333:351–364). This phenomenon occurred on Core Reserve Area 3 (CRA3), a preserved area of tallgrass prairie and woodland on Tinker Air Force Base on the outskirts of Oklahoma City. One of the few remnant populations of *Phrynosoma cornutum* in central Oklahoma occurs on CRA3 (35.415780°N, 97.410975°W; WGS 84), and this population has been studied intensively with visual surveys and radio telemetry (Endriss et al. 2007. Herpetologica 63:320–331; Bogosian et al. 2012. Ecol. Model. 237/238:63–73; Wolf et al. 2013. Herpetologica 69:265–281). We directly observed 10 telemetered *P. cornutum* taking refuge in these drought-induced cracks on multiple occasions during the summer and autumn between 2010 and 2014 (Fig. 1). Several additional *P. cornutum* were suspected of being in cracks based on telemetry signals, but could not be visually confirmed. Various ages of *P. cornutum* were observed using these cracks, including hatchlings (SVL 23–26 mm) and adults of both sexes (SVL 52–72 mm). Cracks were generally only a few centimeters wide at ground level, and the width of the cracks decreased with increasing depth. *P. cornutum* were observed up to 150 mm below ground level. Individuals of all ages were also observed partially

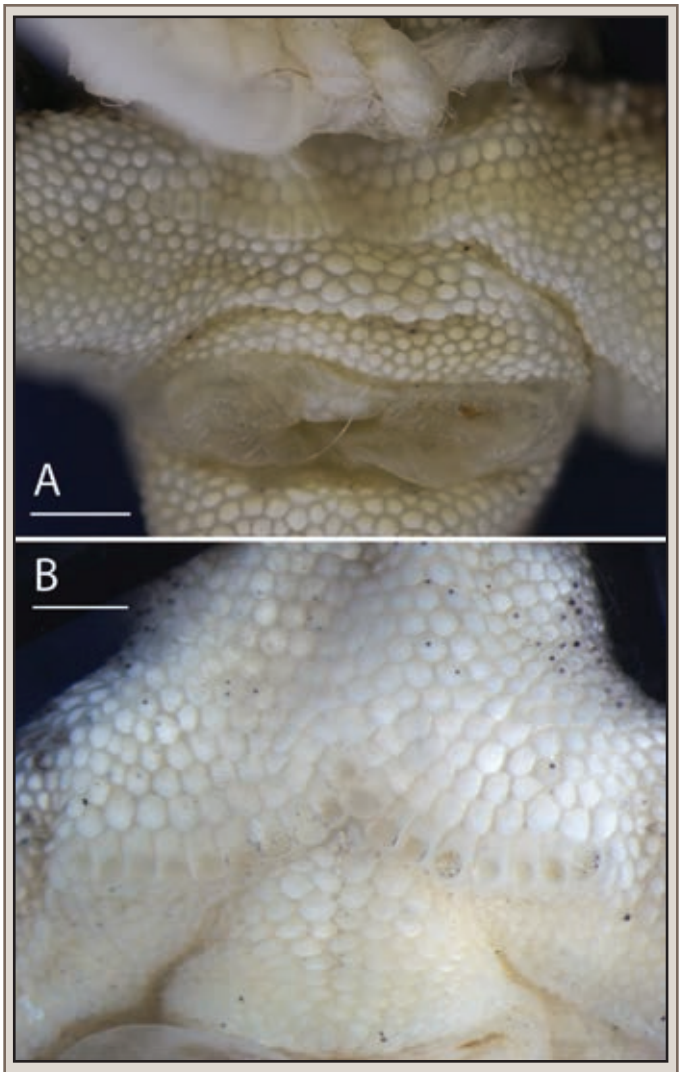

FIG. 1. *Phrynosoma cornutum* utilizing an ephemeral desiccation crack as a refuge.

in or adjacent to cracks, and would seek refuge deeper in cracks upon approach by researchers. Pianka and Parker (1975. Copeia 1975:141–162) suggested that *Phrynosoma* engage in bimodal daily activity patterns during June, July, and August to avoid the heat of the day, which can often exceed 32°C at CRA3. Crack use may represent an escape from heat during summer. However, *P. cornutum* have also been observed using cracks in the autumn during temperatures of 16–21°C suggesting that cracks may also provide refuge from predators, as is indicated by *P. cornutum* seeking shelter in cracks when approached by researchers. To our knowledge, use of desiccation cracks in substrate has not been documented in the literature for *Phrynosoma*, but these refugia seem to represent a valuable, though ephemeral, microhabitat. Such cracks may be especially valuable, given that refugia provided by vegetative cover may be reduced during and soon after times of extreme high heat and low humidity.

***PSEUDOGEKKO DITOY* (Leyte Diminutive False Gecko). MORPHOLOGY.** *Pseudogekko ditoy* is a recently described, secretive species of gecko known only from the islands of Leyte and Samar in east-central Philippines. Few specimens of this species have been encountered or collected, and as such, researchers have had limited ability to detect morphological variation among individuals. The examination of secondary sexual characteristics has been an important tool used to determine the sex of individuals in this genus. Many secondary sexual characteristics exist among lizards, but a widespread diagnostic character used to differentiate sexes is the presence of enlarged, precloacal or femoral pores. Typically, these pores are used to identify males of a species; however, the presence of precloacal pores in females has been documented in several families, including Lacertidae (Khanoon et al. 2013. Zool. Sci. 30:110–117), Liolaemidae (Valdecantos et al. 2014. Acta Herpetol. 9:147–158), and Gekkonidae. Within the family Gekkonidae, females with precloacal pores have been reported for multiple genera, including *Cyrtodactylus* (Bauer et al. 2010. Zootaxa 2570:41–50; Pauwels et al., 2014. Zootaxa 3755:584–594), *Hemiphyllodactylus* (Zug 2010. Smithson. Contr. Zool. 631:1–70), *Hoplodactylus* (Jewell 2006. Identifying Geckos in Otago. Science & Technical Publishing, Department of Conservation. Wellington, New Zealand. 60 pp.), and *Naultinus* (Jewell 2006, *op cit.*). Herein, we report on the first record of precloacal pores in female *Pseudogekko*.

During a recent biodiversity survey from 1 June to 9 July 2014 on Samar Island in the eastern Philippines, we collected two adult *P. ditoy* on leaf litter near stream systems: a single, gravid, adult female (KU 338507) in Municipality of San Jose de Buan, Western Samar Province, Samar Island, Philippines (12.05262°N, 125.03429°E, WGS 84; 209 m elev.), and a single adult male (KU 338508) in Barangay San Rafael, Municipality of Taft, Eastern Samar Province, Samar Island, Philippines (11.80255°N, 125.29276°E, WGS 84; 140 m elev.). The specimens have 18 (female) and 17 (male) small pores in continuous, precloacal series, which are moderately arched anteromedially. The posterior half of the body on the male specimen is damaged; however, comparisons with the pore series of a previously collected adult male (KU 326438, paratype) shows female pores to be smaller in size than male pores (Fig. 1). Recognizing that this character has been used to determine sex in systematic studies of this genus, with the presence of pores recognized to occur in males only (Siler et al. 2014. Herpetol. Monogr. 28:110–139), caution must be taken in future studies concerning the use of this character to determine sex, and gonadal inspection may be necessary for proper validation. Fieldwork was supported by NSF DEB 0743491 and EF-0334952 to RMB, and NSF DEB 0804115 and IOS 1353683 to CDS.

***SPHAERODACTYLUS BROMELIARUM*. SIZE RECORD.** On 30 January 2005, Ariel Rodríguez and Roberto Alonso collected an adult female and two juveniles of *Sphaerodactylus bromeliarum* inside a bromeliad from Yunque de Baracoa, Baracoa Municipality, Guantánamo Province. The adult female (CZACC 4.5657, Herpetological Collection of the Instituto de Ecología y Sistemática, Havana Province, Cuba) measures 28.1 mm snout–vent length (SVL), and has 41 dorsal and 36 ventral scales between axilla and groin, respectively; 54 scales around midbody and 12 fourth toe lamellae. The previously reported maximum length for this species is 24.0 mm SVL, also in another adult female (Peters and Schwartz 1977. Mitt. Zool. Mus. Berlin 48:393–399).

***SPHENOMORPHUS SABANUS* (Sabah Slender Skink). REPRODUCTION.** *Sphenomorphus sabanus* is endemic to Borneo, Southeast Asia, where it is found from lowlands to submontane forests (Das 2010. A Field Guide to the Reptiles of South-East Asia, Myanmar, Thailand, Laos, Cambodia, Vietnam, Peninsular Malaysia, Singapore, Sumatra, Borneo, Java, Bali. New Holland Publishers, UK. 376 pp). It is oviparous and produces clutches of 2–3 eggs (Das 2010, *op. cit.*). In this note I add information on the reproductive biology of *S. sabanus* from a histological examination of gonadal material from the herpetology collection of the Field Museum of Natural History (FMNH), Chicago, Illinois.

A sample of 53 *Sphenomorphus sabanus* from Sabah, (5.2500°N, 117.0000°E) Borneo, Malaysia collected 1986 to 1991, consisting of 31 males (mean SVL = 51.1 mm ± 2.7 SD, range = 44–55 mm), 21 females (mean SVL = 51.3 mm ± 2.3 SD, range = 47–55 mm) and one subadult female (SVL = 44 mm) was examined from the following localities: Lahad Datu District FMNH 230137, 230139, 230141, 230143, 230144, 230150, 230153, 235176, 235180, 235183, 246352; Kota Marudu District FMNH 239790, 239791–239794, 239796, 239798, 239799, 239801, 239803, 239804; Tenom District FMNH 239805, 239806, 239808, 239810, 239811, 239813, 239815–239817, 239819, 239821, 239829, 243830, 243832; Lahad Datu District FMNH 240575, 240577, 240578, 240581, 240584, 240586, 240587, 240589; FMNH 243829, 246338, 246343, 246346, 246348, 246351, 246355; Tawu District FMNH 248517, 248519.

A cut was made in the lower abdominal cavity and the left testis or ovary was removed, embedded in paraffin, cut into 5 µm sections and stained with Harris hematoxylin followed by eosin counterstain. Enlarged follicles (> 3 mm) or oviductal eggs were counted. Histology slides were deposited in FMNH.

The only stage present in the testicular cycle was spermiogenesis in which the lumina of the seminiferous tubules were lined by sperm or clusters of metamorphosing spermatids. The following monthly samples of males were examined: June (N = 4); July (N = 4); August (N = 1); September (N = 2); October (N = 2); November (N = 10); December (N = 8). The smallest reproductively active male (spermiogenesis) measured 44 mm SVL (FMNH 230153) and was collected in December.

TABLE 1. Monthly stages in the ovarian cycle of 21 adult *Sphenomorphus sabanus* from Sabah, Malaysia; * indicates one oviductal female each from July, October, and December were also undergoing concurrent yolk deposition for a subsequent egg clutch.

Month	N	Quiescent	Enlarged follicles	Oviductal eggs > 3 mm
June	1	0	1	0
July	3	0	1	2*
August	1	1	0	0
October	5	0	2	3*
November	5	0	1	4
December	6	1	1	4*

Three stages were present in the ovarian cycle (Table 1): (1) quiescent, no yolk deposition; (2) enlarged follicles > 3 mm; (3) oviductal eggs. Three females with oviductal eggs, one each from July (FMNH 239821), October (FMNH 239794) and December (FMNH 240586) contained concurrent vitellogenic follicles indicating *Sphenomorphus sabanus* can produce multiple clutches in the same year. Mean clutch size (N = 19) was 1.9 ± 0.32 SD, range = 1–2. The smallest reproductively active female (one enlarged follicle > 3 mm) measured 47 mm SVL and was collected in June. One smaller female with quiescent ovaries (FMNH 239794) measured 44 mm SVL and was considered to be a subadult.

Because both males and females (Table 1) were reproductively active at opposite ends of the year (June versus December), it is apparent *Sphenomorphus sabanus* exhibits an extended reproductive cycle. Whether *S. sabanus* reproduces throughout the year will require examination of additional specimens.

I thank Alan Resetar (FMNH) for permission to examine *S. sabanus* and L Lee Grismer (LaSierra University, Riverside, California) for taxonomic verification.

STEPHEN R. GOLDBERG, Whittier College, Department of Biology, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

***TARENTOLA MAURITANICA* (Moorish Gecko). EYE DISEASE.** Of approximately 150 specimens of *Tarentola mauritanica* that we examined in Cádiz Province, Spain, between 1969 and 1971, only one was found to exhibit an eye disease. It was collected 15 August 1970, 13.3 km ESE (bearing 95°; 36.137876°N, 5.555630°W, WGS 84; ~305 m elev.) from Facinas in an area currently within the Parque Natural de Los Alcornocales.

Lymphoreticular cells, derived from bone marrow by stem cell multiplication, circulate through the body as monocytes, and differentiate into histiocytes (tissue macrophages) to become part of the body's mononuclear phagocytic system. Scleritis, an inflammatory disease affecting the sclera, and keratitis, a condition in which the cornea becomes inflamed, often results in perforation of the cornea and complete loss of the eye. Hystiocytic and lymphoplasmacytic scleritis and keratitis, coupled with possible secondary glaucoma, were determined to be responsible for the malady evident in the specimen illustrated (Fig. 1; Histology Report 87059/A, 30 July 2014; Department of Pathology, Necropsy and Forensic Medicine, University of Agricultural Sciences and Veterinary Medicine, Cluj-Napoca, Romania).

Anomalies and eye diseases of captive reptiles have been reviewed in the literature of veterinary medicine (Millichamp et al.

PHOTOS A & B BY S. D. BUSACK; PHOTOS C & D BY G. M. BORZA

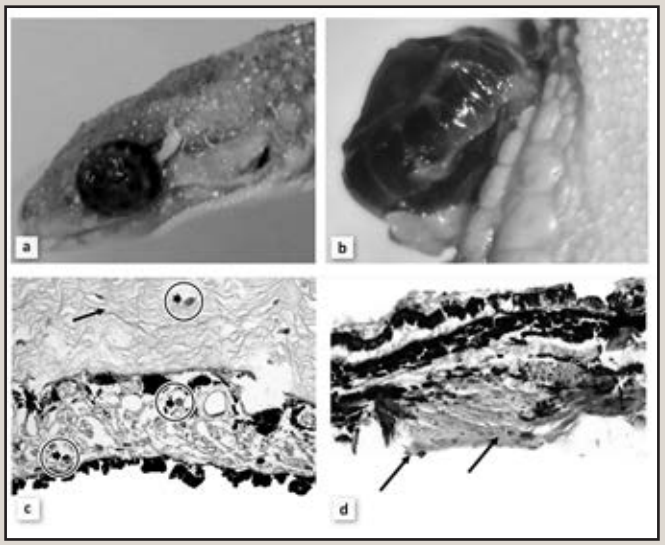

FIG. 1. a) Hystiocytic and lymphoplasmacytic scleritis and keratitis in left eye of a *Tarentola mauritanica* (UCM 44970); b) enlarged ventral view; c) thickened corneal tissue (elongated arrow) with inflammatory cells (encircled arrows) present in the sclera and choroid; d) keratitis with presence of inflammatory cells (arrows).

1983. J. Amer. Vet. Med. Assoc. 183:1205–1212; Sabater and Pérez 2013. Vet. Ophthalmol. 16:47–55) but no information regarding occurrences in natural environments is readily available. This condition was not addressed within either review and, to our knowledge, has not been recorded previously.

We are indebted to Christy McCain and Emily Braker at the Museum of Natural History, University of Colorado, for the loan of the specimen, permission to excise and examine the eye, and for placing several photographs showing different views of this condition in the museum's collections. Liz Bradford (OX•HIP Studio, Raleigh) prepared Fig. 1.

SQUAMATA — SNAKES

***AGKISTRODON CONTORTRIX* (Copperhead). DIET.** *Agkistrodon contortrix* is a medium-sized pit-viper found in the eastern United States (Ernst and Ernst 2002. Snakes of the United States and Canada. Smithsonian Institution Press, Washington D.C. 661 pp.) that feeds on a variety of prey, including mammals, birds, reptiles, amphibians, and a variety of invertebrates (Fitch 1960. Univ. Kansas Publ. Mus. Nat. Hist. 13:85–288; Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex: A Monographic Review. Society for the Study of Amphibians and Reptiles, Oxford, Ohio. 614 pp.). The only species of whiptail (genus *Aspidoscelis*) explicitly reported in the diet of *A. contortrix* is *A. sexlineatus* (Six-lined Racerunner). Here we report an unusual predation event and a novel prey item (*Aspidoscelis gularis*; Common Spotted Whiptail) in the diet.

FIG. 1. *Agkistrodon contortrix* holding both leaves and the autotomized tail of an *Aspidoscelis gularis* in its mouth.

At 1600 h on 27 May 2015, we were walking on a nature trail behind the westbound I-10 Guadalupe County Rest Area in Guadalupe Co., Texas, USA (29.616486°N, 97.805625°W; WGS 84). As we walked, we startled several *Aspidoscelis gularis*, which ran off the trail. One small whiptail ran directly towards a coiled *A. contortrix*, which struck at it. This happened very quickly and we had not noticed the snake beforehand, so we did not have an opportunity to observe the interaction in detail, but the snake must have made contact with the lizard's tail, which autotomized. The lizard immediately ran off at a ~90° angle to the snake, away from the path, and we lost track of it. The snake's mouth had closed over both the lizard's tail, which thrashed vigorously, and the nearby leaves of a small herbaceous plant. Momentarily, the snake was able to partially open its mouth and withdraw its jaws from the plant leaves without dropping the still-moving tail, which it then jaw-walked and, eventually, swallowed.

Consumption of autotomized lizard tails has been documented in snakes, particularly from the stomachs of preserved museum specimens (Greene 1983. Am. Zool. 23:431–441). Medel et al. (1988. Oikos 53:321–324) suggested that tail autotomy represented inefficient predation by snakes and other predators, but when autotomized tails are consumed (as in this case) predators do obtain some nutrition from even a botched predation event. Unpublished data being collected by G. Salmon and H. W. Greene also document *A. gularis* in the diet of *A. contortrix* in central Texas.

ANDREW M. DURSO (e-mail: amdurso@gmail.com) and **KENDALYNN A. MORRIS**, Department of Biology, Utah State University, Logan, Utah 84322, USA.

***AGKISTRODON PISCIVORUS CONANTI* (Florida Cottonmouth). DIET.** *Agkistrodon piscivorus* is a dietary generalist,

having been documented eating a diverse array of taxa (Ernst and Ernst 2011. Venomous Reptiles of the United States, Canada, and Northern Mexico, Vol. 1. Johns Hopkins University Press, Baltimore, Maryland. 352 pp.). In peninsular Florida, *A. p. conanti* lives in sympatry with many nonnative species, some of which have the potential to be included in its wide diet.

On 11 May 2014, at approximately 1100 h, an *A. p. conanti* (total length ca. 38 cm) was observed actively foraging in a shallow pool at the base of a culvert in the Everglades National Park, Miami-Dade Co., Florida, USA (25.519900°N, 80.567023°W; WGS 84). The snake proceeded to capture and swallow headfirst a small (ca. 15 cm) *Clarias batrachus* (Walking Catfish). After swallowing the fish, the snake remained immobile for approximately 15 min. and then left the pool.

This is the first documented instance of *A. p. conanti* feeding upon the nonnative *C. batrachus*. With up to 60 species of nonnative fish species documented in the greater Everglades drainage (Nico and Fuller 1999. Fisheries 24:16–27), it is likely that resident *A. p. conanti* frequently utilize nonnative fish as a food resource. *Clarias batrachus* can potentially be a difficult prey species to subdue, having stinging dorsal and pectoral spines (Ng and Kottelat 2008. Zool. J. Linn. Soc., 153:725-732). Krysko et al. (2010. Herpetol. Rev. 41:348–349) captured an unusually lethargic *Caiman crocodilus*, and attributed the atypical behavior to the *C. batrachus* later found to be lodged in its throat. Being that *A. p. conanti* is a well-known predator of native ictalurid catfishes with similar dorsal and pectoral spines (Ernst and Ernst, *op. cit.*), it is possible that *A. p. conanti* is not susceptible to these anti-predatory morphological traits.

JOSH FRIERS, United States Department of Agriculture Wildlife Services, Homestead, Florida 33030, USA (e-mail: joshfriers@yahoo.com); **JAMES P. FLAHERTY**, Center of Excellence for Field Biology/Department of Biology, Austin Peay State University, Clarksville, Tennessee 37040, USA.

***BOTHROPS LEUCURUS* (Whitetail Lancehead). DIET.** *Bothrops leucurus* is a medium-sized, terrestrial, viperid snake of the *B. atrox* group that is found in the Atlantic Forest of northeastern and eastern Brazil (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Cornell Univ. Press, Ithaca, New York. 870 pp.). The diet of this species consists of small vertebrates with an ontogenetic shift from frog and lizard prey as juveniles to rodents as adults (Lira-da-Silva 2009. Gaz. Med. Bahia 79:56–65).

On 14 June 2012, an adult female *B. leucurus* was collected in Trilha Ecológica do Clube Granjeiro (7.165166°S, 39.261562°W, WGS 84; 708 m elev.), located in the foothills of the Chapada do Araripe, municipality of Crato, Ceará, northeastern Brazil. The snake (SVL = 844 mm; tail length = 126 mm; 325 g) was euthanized and during the fixing process expelled an adult male *Atractus ronnie* (Fig. 1; SVL = 212 mm; Tail length = 28 mm; 6.2 g). Both the *B. leucurus* and the *A. ronnie* were deposited in the Coleção Herpetológica da Universidade Regional do Cariri (URCA-H 3478, 6204, respectively).

Atractus ronnie is a small snake distributed in areas of Atlantic forest in the semiarid Caatinga in Serra de Baturité, Planalto da Ibiapaba and Chapada do Araripe, state of Ceará, Brazil (Passos et al. 2007. Copeia 2007:788–797; Loebmann et al. 2009. Biotemas 22:169–173), and is listed as Endangered by the IUCN – the World Conservation Union (IUCN 2015. IUCN Red List of Threatened Species. Version 2015.1. <www.iucnredlist.org> 09 June 2015). Ophiophagy is rare in *B. leucurus*, with only one snake, *Micrurus corallinus*, recorded as prey (Fagundes et al. 2009. Bol. Mus. Biol. Mello Leitão 25:67–71).

Antônio Luiz, 1161, Bairro do Pimenta, CEP 63105-100, Crato, Ceará, Brazil.

***BOTHROPS JARARACA* (Jararaca). PREDATION.** The genus *Bothrops* comprises ca. 40 species that use cryptic coloration and potent venom as defenses against predators (Sasa et al. 2009. Toxicon 54:904–922). Therefore, we know little about natural predators of free-living *Bothrops*. Occasional records of predators include birds, snakes, and mammals (Sazima 1992. *In* Campbell and Brodie [eds.], Biology of Pitvipers, pp. 199–216. Selva, Tyler, Texas; Sasa et al., *op. cit.*).

Here we report a case of predation on *Bothrops jararaca* in Parque Estadual da Ilha Grande (23.1781°S, 44.1860°W, WGS 84; 23 m elev.), an island of Atlantic forest southeast of Rio de Janeiro, Brazil. On 29 September 2014, at 0900 h, LMV observed a *Buteogallus lacernulatus* (White-necked Hawk) hunting in the litter of secondary forest. The hawk then flew up with a snake in its talons and perched on a branch ca. 3 m high above the ground (Fig. 1). The hawk held the snake by its neck and after ca. 5 min. flew away with the snake in its talons. The snake was identified as *B. jararaca* by the spot coloration pattern typical of the species (Sazima 1988. Mem. Inst. Butantan 50:83–89). Considering that the tarsus of *B. lacernulatus* is ca. 80 mm in length (M.A.S. Alves, unpubl. data), we estimate that the snake was an adult of at least 60 cm in total length.

There are records of predation on *B. jararaca* by *Clelia plumbea* (Mussurana; Pinto and Lema 2002. Iheringia, Zool. 92:9–19) and *Didelphis albiventris* (White-eared Opossum; Oliveira

PHOTO BY L. M. VALLEJOS

FIG. 1. An adult *Bothrops jararaca* held in the talons of *Buteogallus lacernulatus* (White-necked Hawk).

and Santori 1999. Stud Neotrop. Fauna E 34:72–75), but the only known avian predators are *Rupornis magnirostris* (Roadside Hawk; Sazima 1992, *op. cit.*), *Buteogallus urubitinga* (Great Black Hawk; Carvalho 2006. Rev. Bras. Ornitol. 14:445–448), and *Geranoaetus albicaudatus* (White-tailed Hawk; Motta et al. 2010. Biota Neotrop. 10:355–159). The diet of *B. lacernulatus* is not well known, but is thought to be variable. Although arthropods may predominate, there are reports of consumption of snakes and other vertebrates by this hawk (Thiollay 1994. *In* del Hoyo et al. [eds.], Handbook of the Birds of the World, vol. 2, pp. 52–205. Lynx Editions, Barcelona). However, our record is the first to identify a snake preyed upon by *B. lacernulatus* to species level.

We are grateful to C. F. D. Rocha, D. Vrcibradic, J. A. L. Pontes, G. R. Wink, and D. C Passos for the snake's identification, and UERJ for logistical help. We thank Lulu Stader for the English review. To Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) for the scholarship to LMV (process 190594/2013-6) and grant to MASA (process 305798/2014-6). We also thank to Fundação Carlos Chagas Filho de Amparo à Pesquisa do Estado do Rio de Janeiro (FAPERJ) for the scholarship to EAR, and grant to MASA (E-26/102837/2012).

***CLELIA SCYTALINA* (Mexican Snake-eater) DIET.** *Clelia scytalina* is known to consume snakes, frogs, and lizards (García and Ceballos 1994. Guía de Campo de los Reptiles y Anfibios de la Costa de Jalisco, México. Fundación Ecológica de Cuixmala AC, Instituto de Biología, UNAM, México. 184 pp.; Pérez-Higareda et al. 2007. Serpientes de la Región de los Tuxtlas, Veracruz, México.

FIG. 1. Juvenile *Clelia scytalina* with four partially digested *Peromyscus maniculatus* (North American Deer Mice).

Guía de Identificación Ilustrada. UNAM, México. 189 pp.). Herein we report the first account of a *C. scytalina* consuming *Peromyscus maniculatus* (North American Deermouse) from the municipality of Cuauhtemoc, Colima, Mexico.

On 07 August 2014, a juvenile *C. scytalina* was found dead on the Cuauhtemoc–Buenavista freeway in the municipality of Cuauhtemoc, Colima, Mexico (19.292922°N, 103.595868°W, WGS 84; elev. 790 m). While the snake was being preserved, four partly-digested young *P. maniculatus* (identified by the shape of the skull and the feet in the most intact individual) were found in the stomach (Fig. 1). The freeway where the snake was found is surrounded by patches of tropical deciduous forest and sugar cane and rice fields.

***COLUBER CONSTRICTOR* (North American Racer). FORAGING BEHAVIOR.** Observations of non-marine snakes foraging in intertidal areas are rare. On 10 May 2015, at 1330 h, a *Coluber constrictor* was observed actively foraging within the intertidal zone (Fig. 1) at the north end of Christy Beach on the west end of Santa Cruz Island, California, USA. This is the only documented record of *C. constrictor* foraging within the intertidal zone. *Coluber constrictor* is found throughout much of California, but is recorded from only one California Island—Santa Cruz (Schoenherr et al. 1999. Natural History of the Islands of California. Univ. California Press, Berkeley. 491 pp.). Observations of *C. constrictor* are relatively rare even in upland regions of the island, and conferring

PHOTO BY J. FENERTY

FIG. 1. *Coluber constrictor* hunting within the intertidal zone on West Santa Cruz Island, California, USA.

with island biologists who have worked on the island for over 30 years, *C. constrictor* has never been observed in the intertidal region. Four years of record drought and increased competition with other wildlife such as the recovering population (N = 1200) of the Federally Endangered *Urocyon littoralis santacruzae* (Santa Cruz Island Fox) are suspected of driving *C. constrictor* to forage within the more productive intertidal habitats along the coast of the island due to the lack of prey in terrestrial habitats. This individual was observed tracking *Tegula* sp. (turban snails) and *Pachygrapsus crassipes* (Rock Shore Crab) as they moved across pools within the intertidal; however, no feeding was observed.

JOHN J. KNAPP, The Nature Conservancy, 532 East Main Street, Suite 200, Ventura, California 93001, USA (e-mail: jknapp@tnc.org); **JUDY FENERTY**, California Native Plant Society – Santa Clara Valley Chapter, 3921 East Bayshore Road, Palo Alto, California 94303, USA (e-mail: judy@fenerty.com).

COLUBER FLAGELLUM **[=** ***MASTICOPHIS FLAGELLUM*****] (Coachwhip). ULTRAVIOLET (UVB) EXPOSURE.** *Coluber flagellum* is an active diurnal snake that thermoregulates to maintain a relatively stable body temperature (≈ 32°C) when active (Hammerson 1989. J. Therm. Biol. 14:219–224; Secor and Nagy 1994. Ecology 75:1600–1614). In spring and autumn *C. flagellum* basks in the sun upon emergence in the morning to raise its body temperature and then maintains its body temperature at a steady level throughout the day by moving among thermal microenvironments. During the summer months in more open desert habitats *C. flagellum* retreats underground during the middle of the day (Jones and Whitford 1989. Southwest. Nat. 34:460–467). Although the thermal environment and thermoregulation has been investigated for this species, its exposure to solar ultraviolet-B (UVB) to our knowledge remains unreported in the literature. While basking in the sun is an important source of heat for many diurnal lizards and snakes during thermoregulation, it also exposes them to UVB radiation. The effects of UVB exposure can be both detrimental, causing tissue damage (Chang and Zheng 2003. J. Photochem. Photobiol. B 72:79–85), and beneficial, facilitating vitamin D production (Ferguson et al. 2005. Physiol. Biochem. Zool. 78:193–200; Acierno et al. 2008. Am. J. Vet. Res. 69:294–297). Knowledge of the natural UVB environment is important from the point of view of conservation and captive management of amphibians and reptiles (Antwis and Browne 2009. Comp. Biochem. Physiol. A 154:184–190; Ferguson et al. 2010. Zoo Biol. 29:317–334).

During field studies in West Texas and New Mexico from 2008 through 2012, we recorded the UVB exposure and environmental temperatures of ten *C. flagellum* during the day (Table 1). UVB irradiance was measured using two hand-held broad-band UVB meters, the Solarmeter 6.2 (displays µW / cm^2), and Solarmeter 6.5 (displays ultraviolet index [UVI]) (Solartech, Inc. Harrison Township, Michigan). These meters are sensitive to irradiance within the UV range (280–400 nm) and respond most strongly to wave lengths in the UVB range below 320 nm. We took readings by placing the base of the unit on the substrate and orienting the flat sensor disk on the top of the unit (≈ 10.8 cm from the base) toward the sun or to the adjacent open sky. We obtained substrate temperature (T_s) holding a digital infrared thermometer (Raytek PM-30' Santa Cruz, California) within 5-cm of the substrate and air temperatures (T_a), holding a cloacal thermometer (Miller and Weber, Inc., Ridgewood, New York), with bulb shaded, 5-cm above the substrate. The cloacal thermometer was also used to record cloacal body temperature (T_b; for one snake only).

The average UV index of exposure during the day was 4.69 with a median of 3.15 (Table 1). This is the highest voluntary

TABLE 1. Temperature and ultraviolet light exposure of ten *Coluber flagellum* encountered in Texas and New Mexico. T_s = substrate temperature (°C); T_a = air temperature (°C); T_b = body temperature (°C). All data were recorded at the exact site of discovery of each snake. All snakes were immobile when first sighted except the last one.

exposure yet recorded for a diurnally active snake and the median value qualifies it as a UVB zone-4 species (see Ferguson et al. 2010, *op. cit.* for definition of the four UVB zones, zone-4 being the highest).

We thank Chip Ruthven, other officials of the Matador Wildlife Management Area, Lee Fitzgerald, and Dan Leavitt for help with research projects that made these observations possible. Partial funding for the research was provided by three Faculty Emeritus Research grants from Texas Christian University to GWF.

GARY W. FERGUSON (e-mail: g.ferguson@tcu.edu), **ANDREW M. BRINKER, WILLIAM H. GEHRMANN,** Department of Biology, P.O. Box 298930, Texas Christian University, Fort Worth, Texas 76129, USA.

COLUBER TAENIATUS **[=** ***MASTICOPHIS TAENIATUS*****] (Striped Whipsnake). RAIN-HARVESTING.** Rain-harvesting behavior—the collection and consumption of water (rain or condensation from fog) on the body or from environmental surfaces—has been reported in lizards (e.g., Schwenk and Greene 1987. J. Herpetol. 21:134–139; Sherbrooke 1990. J. Herpetol. 24:302–308; Sherbrooke 1993. J. Herpetol. 27:270–275; Peterson 1998. Southwest. Nat. 43:391–394; Veselý and Modrý 2002. J. Herpetol. 36:311–314; Sherbrooke 2004. Amphibia-Reptilia 25:29–39), several species of viperid snakes (Robinson and Hughes 1978. Ann. Transvaal Mus. 31:189–193; Aird and Aird 1990. Bull. Chicago Herpetol. Soc. 25:217; Ashton and Johnson 1998. Herpetol. Rev. 29:170; Andrade and Abe 2000. Amphibia-Reptilia 21:485–492; Cardwell 2006. Herpetol. Rev. 37:142–144; Rorabaugh 2007. Sonoran Herpetol. 20[12]:128–129; Repp and Schuett 2008. Southwest. Nat. 53[1]:108–114; Glaudas 2009. Southwest. Nat. 54[4]:518–521; Mata-Silva et al. 2014. Southwest. Nat. 59[2]:303–304; Murray and Irish 2015. Herpetol. Rev. 46[2]:266), and one natricid snake (Miller 1985. Herpetol. Rev. 16:71). Nearly all of these reports were for species occurring in xeric environments.

On 10 September 2011, at 2130 h during a thunderstorm, RP encountered an adult (Total length ≤ 1 m) *Masticophis taeniatus* on a paved road ca. 21 km ENE of Big Pine on the xeric western slopes of the White Mountains, Inyo Co., California, USA. The snake had not been on the road 30 min earlier when RP passed this location. The snake was observed with its head directed upward and mouth agape. It appeared to be capturing large raindrops, which were then swallowed. *Masticophis taeniatus* is a diurnal species, whose nocturnal activity was presumably triggered by this rare late-summer rainfall event. To our knowledge, previous reports of rain-harvesting in snakes have mostly involved viperids that drank water that had accumulated in the depressions formed by a tightly coiled body.

RICHARD PORTER, 700 Gibson Drive, Apt. 304, Roseville, California 95678, USA; **ROBERT W. HANSEN**, 16333 Deer Path Lane, Clovis, California 93619-9735, USA (e-mail: hansenranch2@gmail.com).

CROTALUS DURISSUS **(South American Rattlesnake). SWIMMING BEHAVIOR TO CROSS GEOGRAPHICAL BARRIER.** *Crotalus durissus* is the only rattlesnake found in South America (Wüster et al. 2005. Mol. Ecol. 14:1095–1108). Divided into five subspecies in Brazil (SBH 2015. Sociedade Brasileira de Herpetologia), this savannah-associated species is invading disturbed areas of other biomes, including the Atlantic Forest (Bastos et al. 2005. Rev. Bras. Zool. 22:812–815). Rivers are strong geographical barriers for many species (Ribas et al. 2011. Proc. R. Soc. B. 1729:681–689). However, phylogenetic inferences showed that this species has low genetic divergence between populations across its wide distribution (Wüster et al. 2005. Mol. Ecol. 14:1095–1108). On 4 April 2015 at 1207 h we observed a *C. durrisus* crossing the Rio Grande (49.258578°W, 20.256825°S; WGS 84), municipality of Fronteira, state of Minas Gerais, southeastern Brazil, which is 310 m wide at that point. Although rattlesnakes are known to be adept swimmers, this snake's willingness to cross such a large expanse of open water provides direct evidence for these features not being a strong geographical barrier for this species.

FIG. 1. Observation point of *Crotalus durissus* in Rio Grande River, state of Minas Gerais, Brazil.

LUCAS FERRANTE, Instituto Boitatá Etnobiologia e Conservação da Fauna, 74265-310 Goiânia, GO, Brazil (e-mail: lucasferrante@hotmail.com); **RAFAEL MENEGUCCI**, Universidade Federal de Alfenas (Unifal), 37130-000 Alfenas, MG, Brazil (e-mail: Rafael_menegucci@hotmail.com); **IBERE FARINA MACHADO**, Instituto Boitatá Etnobiologia e Conservação da Fauna, 74265-310 Goiânia, GO, Brazil (e-mail: iberemachado@gmail.com).

CROTALUS HORRIDUS **(Timber Rattlesnake). DIET.** The diet of the predominantly terrestrial *Crotalus horridus* is composed mostly of small mammals; birds make up only a small percentage of known prey items (Clark 2002. J. Herpetol. 36:494–499, Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, Washington D.C. 668 pp.). Herein, we report the first documented instances of *C. horridus* predation on two bird species, *Molothrus ater* (Brown-headed Cowbird) and *Cardinalis cardinalis* (Northern Cardinal). Both observations occurred 8.3 km NNW of Pembroke, Bulloch Co., Georgia, USA (32.210084°N,

FIG. 1. Adult *Crotalus horridus* from Bulloch Co., Georgia, consuming a *Molothrus ater* (Brown-headed Cowbird).

81.633875°W; WGS 84). At 1755 h on 17 May 2012, GH observed an adult *C. horridus* (SVL = ca. 95 cm) kill and consume an adult *M. ater* (Fig. 1). The bird was initially ambushed and struck by the snake inside a small children's plastic pool where the snake sat coiled in ca. 1.5 cm of water. The *M. ater* died approximately 1 m from where it was struck by the snake. Approximately 2 min after the strike, the snake left the pool and crawled to the now dead bird and ingested it.

At the same locality at 0850 h on 30 August 2014, GH observed an adult male *C. horridus* (SVL = ca. 120 cm) kill and consume a *C. cardinalis*. In this instance, the rattlesnake ambushed the bird on the ground beneath a hanging bird feeder. The bird died nearly instantly ca. 1 m from the snake. Approximately 10 min after the bite, the snake crawled to the bird and ate it. After striking mammalian prey, *C. horridus* will typically release the animal and later begin a chemical search to locate and consume it. Presumably it is more difficult to conduct a chemical search to locate potentially airborne avian prey. Thus, it is interesting that both birds in the current observation were released, but injected with enough venom to prohibit them from traveling far from where they were struck.

GREG HAMMERSTEIN, 774 Burnsed Road, Pembroke, Georgia, USA (e-mail: gahammerstein@gmail.com); **DAVID A. STEEN**, Department of Biological Sciences, Auburn University, 1090 South Donahue Drive, Auburn, Alabama, USA; **DIRK J. STEVENSON**, The Orianne Society, 414 Club Drive, Hinesville, Georgia, USA (e-mail: dstevenson@oriannesociety.org).

***CROTALUS HORRIDUS* (Timber Rattlesnake), *AGKISTRODON CONTORTRIX* (Copperhead), *THAMNOPHIS SIRTALIS* (Common Gartersnake), *NERODIA SIPEDON* (Northern Watersnake), *DIADOPHIS PUNCTATUS* (Ring-necked snake), *STORERIA DEKAYI* (Dekay's Brownsnake). AGGREGATION.** On 12 days between 28 July and 2 October 2009, I watched up to six snake species simultaneously occupy a single hollow log (Figs. 1, 2), 0.8 km from the start of the Little River Trail within the Great Smoky Mountains National Park, Tennessee, USA. Eleven total snakes was the greatest daily emergence (Fig. 2) and although no snakes were captured, all appeared to be mature adult size. On 25 August 2009, I saw what I believed to be the resident rattlesnake (same color and size), dead along the stream's edge. Some large single-species aggregations of snakes are well-known and are usually related to mating or hibernation (Gregory et al. 1987. *In* Seigel et al. [eds], Snakes: Ecology and Evolutionary Biology, pp. 366–395. Macmillan, New York; Ford and Burghardt 1993. *In* Seigel and Collins [eds], Snakes: Ecology and Behavior, pp. 117–164. McGraw-Hill, New York), but intraspecific aggregations and social behavior of snakes are poorly understood. Given that this aggregation occurred during the summer and included multiple species that feed on a wide array of different prey, thermoregulation or protective cover are potential drivers of this aggregation.

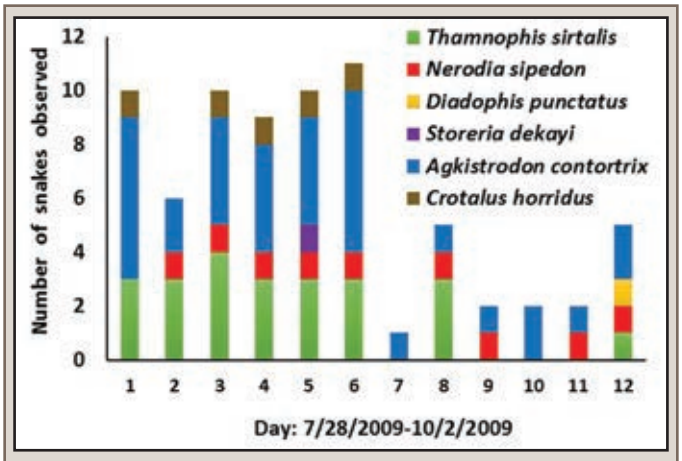

FIG. 2. Daily observations of snakes at the "Snake Log," Great Smoky Mountains National Park, Tennessee, USA, in 2009.

STEVEN L. PITTS, Eastern New Mexico University, Portales, New Mexico 88130, USA; e-mail: steven.pitts@enmu.edu.

***CROTALUS OREGANUS HELLERI* (Southern Pacific Rattlesnake). DIET / SCAVENGING.** *Crotalus oreganus helleri* is a large pitviper found in southwestern California, USA, and adjacent Mexico (Ernst and Ernst 2002. Snakes of the United States and Canada. Smithsonian Institution Press, Washington D.C. 661 pp.), and feeds mostly on endotherms, especially mammals. Here we report evidence that, like other pitvipers, including *C. o. oreganus* (Dornburg and Weaver 2009. Northwest. Nat. 90:55–57) and *C. o. lutosus* (Diller 1990. J. Herpetol. 24:95–97), *C. o. helleri* sometimes scavenges dead prey in the wild.

FIG 1. *Crotalus horridus*, *Thamnophis sirtalis*, and *Agkistrodon contortrix* emerging from the "Snake Log," Great Smoky Mountains National Park, Tennessee, USA in 2009

FIG. 1. *Crotalus oreganus helleri* scavenging posterior portion of a *Sylvilagus bachmani* (Western Brush Rabbit) carcass.

At 1500 h one day in late March 2009, one of us (JMG) found and photographed an adult *C. o. helleri* feeding on the posterior portion of a *Sylvilagus bachmani* (Western Brush Rabbit) carcass at Simi Valley, Ventura Co., California, USA (34.223611°N, 118.777778°W; WGS 84). The snake was at the edge of a fire road underneath a probable hawk perch. The rabbit had clearly been killed and partially eaten by another predator, likely a hawk, because its intestines, forelimbs, and head were missing, and the exposed flesh of the rabbit was visibly dry. The snake continued ingesting the carcass despite becoming agitated, and was left alone.

Carrion feeding by wild snakes has been documented numerous times, particularly in pit vipers (DeVault and Krochmal 2002. Herpetologica 4:429–436). Most of these observations involve scavenging of road-killed carcasses (e.g., Durso et al. 2010. Herpetol. Rev. 41:94), whereas this appears to be an instance of scavenging a natural carcass. Most scavenging events are probably overlooked because scavenged carcasses are difficult to differentiate from live prey. Snakes' exceptionally low metabolic demands make it possible for them to capitalize on irregular, low-risk meals in a way that may be unrealistic for many endothermic predators.

JULIE M. GOLLA, Department of Wildland Resources, Quinney College of Natural Resources, Utah State University, Logan, Utah 84321, USA (e-mail: jmgolla@gmail.com); **ANDREW M. DURSO**, Department of Biology, Utah State University, Logan, Utah 84322, USA (e-mail: amdurso@gmail.com).

***CRYPTOPHIS NIGRESCENS* (Eastern Small-eyed Snake). DIET.** Small Australian elapids such as *Cryptophis nigrescens* are rarely encountered consuming novel prey items. Most of these smaller species feed on a variety of skinks; however individuals have occasionally been detected preying on larger serpentiforms such as the legless lizard *Pygopus lepidopodus* (Michael et al. 2014. Vic. Nat. 131:186–187). Even rarer is opportunistic ophiophagy. To our knowledge only one study documents this. Shine (1984. J. Herpetol. 18:33–39) analyzed gut contents of *C. nigrescens* museum specimens from across the species range. Of 560 specimens, only one Queensland specimen contained an unidentified species of blindsnake.

On 17 January 2015 at 0125 h (20°C, several hours after light rain), we observed a *C. nigrescens* (total length ca. 60 cm) along a stretch of unsealed road in the Myall River State Forest (32.380°S, 152.137°E, WGS 84; 62 m elev.) near Bulahdelah, New South Wales, Australia. On closer inspection, the *C. nigrescens* was biting an *Anilios nigrescens* (= *Ramphotyphlops nigrescens*) (total length ca. 25 cm) mid-body. The blindsnake was already dead, suggesting successful envenomation. When we approached, the *C. nigrescens* fled a short distance with the blindsnake in its mouth. Once undisturbed, it proceeded to swallow the blindsnake head first over the course of ca. 3 min (Fig. 1). This observation highlights the broad diet of *C. nigrescens*, and allowed us to verify the species of blindsnake predated. This is the second recorded observation of blindsnakes as a diet item and the first time it has been recorded in New South Wales, Australia.

FIG. 1. *Cryptophis nigrescens* consuming an *Anilios nigrescens* in Myall River State Forest, New South Wales, Australia.

DAMIAN LETTOOF, University of Sydney, New South Wales, Australia (e-mail: dlettoof@hotmail.com); **SAMANTHA K. TRAVERS**, Bensville, New South Wales, Australia (e-mail: samantha.k.travers@gmail.com).

***DENDRELAPHIS SCHOKARI* (Schokar's Bronzeback). PREDATION.** Colubrid snakes of the genus *Dendrelaphis* range from Pakistan in the west, to the northern and eastern coast of Australia in the east and south, and to southern China in the north. They are slender, diurnal, and arboreal snakes that mainly feed on lizards and amphibians (Van Rooijen and Vogel 2008. Contrib. Zool. 77:33–43). *Ceylonthelphusa sentosa* is an endemic, Least Concern (LC), species of freshwater crab found in southern part (Galle) of Sri Lanka (Bahir et al. 2005. Raffles Bull. Zool. 12:47–75). On 14 December 2014, around 1355 h, in a stream in the Ritigala Strict Nature Reserve (SNR), Sri Lanka (8.1050°N, 80.6591°E, WGS 84; elev. 576 m), we observed an adult *C. sentosa* (6 cm carapace width) holding on to the tail of an adult *D. schokari* (total length ca. 55 cm; Fig. 1). The snake was trying to escape from the crab by vigorous body movements. We observed this struggle for nearly 5 min and in the end the crab tried to drag the snake to its hole (Fig. 1). However, due to our presence, the crab was disturbed and released the snake's tail. According to our literature survey, this seems to be the second record (Greene 1997. Snakes: the Evolution of Mystery in Nature. University of California Press,

FIG. 1. A) Adult *Ceylonthelphusa sentosa* trying to drag *Dendrelaphis schokari* in to its burrow. B). *Dendrelaphis schokari* trying to escape from the crab.

Berkeley, California. 99 pp.) of an attempted predation of a snake by a freshwater crab.

This study was funded by Biodiversity Secretariat (2013). We thank the Wildlife Department for the research permits (WL/3/2/73/13). We are grateful to Kanishka Ukuwela for identification of the snake, and Gayan Abeysinghe for help in identification of the freshwater crabs, which were collected during a field visit to the Ritigala SNR.

H. K. S. DE ZOYSA (e-mail: dezoysahks@yahoo.com), **D. P. SAMARASINGHE,** and **S. WICKRAMASINGHE**, Department of Biological Sciences, Rajarata University of Sri Lanka, Mihintale, Sri Lanka (e-mail: sriwick@gmail.com).

***DIPSAS CATESBYI* (Catesby's Snail-eater). DEFENSIVE BEHAVIOR.** Snakes can exhibit a suite of defensive behaviors to protect themselves against a wide variety of predators (Greene 1979. Experientia 35:747–748). *Dipsas catesbyi* is a nocturnal arboreal dipsadid snake found in humid tropical forest from lowlands to mountainous areas, including forest edges (Kornacker et al. 2010. *In* The IUCN Red List of Threatened Species 2010. <www.iucnredlist.org> Accessed 28 March 2015). This species is widely distributed in the Amazon region, and has an isolated population in the Atlantic Forest of southeastern Bahia, Brazil (Argôlo 2004. As Serpentes dos Cacauais do Sudeste da Bahia. Editus, Ilhéus, Bahia. 260 pp.). On 26 March 2015, at 0015 h, we encountered an adult *D. catesbyi* on the forest floor of an area of Atlantic Forest at Michelin Ecological Reserve (13.816667°S, 39.133333°W; SAD 69), Igrapiúna municipality, Bahia, Brazil. The *D. castebyi* first displayed immobility, followed by dorsoventral flattening of the body. When touched, the snake raised the anterior portion of the body (ca. 200 mm), keeping the body flattened and expanding its head to simulate a triangular shape (Fig. 1). The snake held this position for several minutes while moving, always trying to escape. Head elevation and triangulation tend to be more common defensive behaviors in arboreal snake species, whereas dorsoventral body depression is more common in terrestrial species (Martins et al. 2008. South Am. J. Herpetol. 3:58–67). Dorsoventral flattening has been recorded in other arboreal *Dipsas* species: *D. indica* and *D. pavonina* (Martins and Oliveira 1998. Herpetol. Nat. Hist. 6:78–150). The only previously reported defensive behavior of *D. catesbyi* was head triangulation (Cadle and Myers 2003. Am. Mus. Novit. 3409:1–47).

FIG. 1. Defensive behavior of *Dipsas catesbyi*: A) dorsoventral flattening followed by raising of the anterior portion of the body; B) detail of the head triangulation.

We thank the Center of Biological Studies of Michelin Ecological Reserve for logistical support. This project was funded by the Rede BioM.A. Inventários: Padrões de diversidade, biogeografia e endemismo de espécies de mamíferos, aves, anfíbios, drosófilas e parasitos na Mata Atlântica (CNPq—Processo: 457524/2012-0).

EUVALDO MARCIANO-JR (e-mail: euvaldo.marciano@gmail.com), **CAIO VINICIUS DE MIRA-MENDES, IURI RIBEIRO DIAS, FRANCISCO FONSECA RIBEIRO DE OLIVEIRA,** Universidade Estadual de Santa Cruz – UESC, Campus Soane Nazaré de Andrade, Rodovia Jorge Amado, Km 16, Bairro Salobrinho, CEP 45662-900, Ilhéus, Bahia, Brazil; **LEANDRO DE OLIVEIRA DRUMMOND**, Universidade Federal do Rio de Janeiro, Departamento de Ecologia, Laboratório de Vertebrados, CEP 21941-901, Rio de Janeiro, Rio de Janeiro, Brazil.

***ERYTHROLAMPRUS MILIARIS* (Watersnake). PREDATION.** Fishes are uncommonly cited as predators of snakes (Greene 1997. Snakes: the Evolution of Mystery in Nature. University of California Press, Berkeley. 351 pp.). On 28 April 2015 at 1600 h, an adult of the predatory fish *Hoplias malabaricus* (Trahira; Characiformes: Erythrinidae; Total length = 405 mm; mass = 1000 g) was caught in an artificial pond surrounded by Atlantic Forest at municipality of Registro, São Paulo State, Brazil (24.2836°S, 47.5510°W, WGS 84; 46 m elev.). During dissection we found a juvenile *Erythrolamprus miliaris* (SVL = 225 mm; Tail length = 40 mm; 6.6 g) in the stomach (Fig. 1). Considering the broad distribution of this predator in South America (Oyakawa 2003. *In* Reis et al. [eds.], Check List of the Freshwater Fishes of South and Central America, pp. 238–240. Edipucrs, Porto Alegre) as well as the distribution and habitat preferences of *E. miliaris* (Gans 1964. Am. Mus. Novit. 2178:1–58; Michaud and Dixon 1989. Herpetol. Rev. 20:39–41), this may not be a rare event. Both predator and prey were deposited in the Ichthyology collection of the UNESP, Campus Registro (CIR 002 and CIR 003, respectively), State of São Paulo, Brazil.

We thank the staff of "Pesqueiro Paraíso" and Cleber Mikio Rosa Imano for help with fieldwork.

11900-000, Registro, SP, Brazil; **MARCELO RIBEIRO DUARTE**, Laboratório de Coleções Zoológicas, Instituto Butantan, Av. Vital Brazil, 1500, CEP 05503-900, São Paulo, SP, Brazil (e-mail: marcelo.duarte@butantan.gov.br).

***FURINA TRISTIS* (Brown-headed snake). DIET.** *Furina tristis* is a small (<1 m), poorly known elapid found in northeastern Australia and southern Papua New Guinea. A single study has examined the life-history attributes and gut content of 37 specimens held in the collections of Australian museums (Shine 1981. J. Herpetol. 15:219–224). Of these specimens, only four prey items were recovered, all of which were scincid lizards.

At 2012 h on 05 March 2015 (air temperature 25°C), we observed a male *F. tristis* (total length = 82 cm; 131 g) crossing a road within semi-deciduous mesophyll vine forest in the Lockerbie scrub (10.768°S, 142.503°E, WGS 84; 94 m elev.) Cape York Peninsula, Queensland, Australia. The *F. tristis* was holding a dead *Anilios* (*Ramphotyphlops*) *polygrammicus* (gravid female; total length = 49 cm; 46 g) in its mouth at mid-body. The *F. tristis* attempted to escape with the blindsnake when approached, but dropped it after moving several meters. Upon closer inspection, we observed that the blindsnake had several wounds along its body, including on the head and tail. The wounds were very deep and wide, and were unlikely to have been inflicted by the snake (which would be expected to make a series of small punctures; Fig 1). Because of these wound characteristics we are confident that the blindsnake was dead when the *F. tristis* found it. Given the size and shape of the wounds inflicted on the blind snake we hypothesize that it was attacked by a rodent.

A review of literature for wild snakes exhibiting scavenging behavior recorded 26 species representing five families, only one of which was an elapid (*Pseudechis australis*; DeVault and Krochmal. 2002. Herpetologica. 58:429–436). Known blindsnake predators are *Vermicella annulata* (Bandy-bandy Snakes; Shine 1980. J. Herpetol. 14:71–77), owls (Gehlbach and Baldridge 1987. Oecol. 71:560–563), toads (Pizzatto et. al. 2012. Herpetol. Rev. 43:469–470), and potentially rodents (based on our observation). This note is important because it identifies a novel prey item for *F. tristis* and reveals scavenging behavior in this species, although it is unknown with what regularity this behavior occurs.

FIG. 1. Wounds inflicted on *Anilios polygrammicus* left: anterior body, middle: tail/vent, right: head.

DAMIAN LETTOOF, University of Sydney (e-mail: dlettoof@hotmail.com); **DANIEL NATUSCH,** University of Sydney (e-mail: d_natusch_14@hotmail.com).

***GEOPHIS RHODOGASTER* (Rosebelly Earth Snake). REPRODUCTION.** *Geophis rhodogaster* occurs at intermediate elevations from southern Chiapas, Mexico to southwestern Honduras and northwestern El Salvador (McCranie 2011. The Snakes of Honduras, Systematics, Distribution, and Conservation. Society for the Study of Amphibians and Reptiles, Ithaca, New York. 714 pp.). I know of no reports on the reproduction of *G. rhodogaster* other than that it is oviparous (McCranie, *op. cit.*). In this note I report results of a histological examination of gonadal material from *G. rhodogaster* museum specimens.

A sample of 36 adult *G. rhodogaster* consisting of 19 males (mean SVL = 213.4 mm ± 14.9 SD, range = 181–240 mm) and 17 females (mean SVL = 239.1 mm ± 15.9 SD, range = 216–267 mm) collected between 6 July and 4 August 1965 in Guatemala, Departamento Chimaltenango, Acatenango Volcano, Quisache (14.5008°N, 90.8758°W, WGS 84, elev. ca. 1750 m) and deposited in the University of Colorado Museum of Natural History (UCM), Boulder, Colorado, USA was examined: UCM 30673, 30680, 30682, 30684, 30687–30689, 30693, 30696, 30701, 30705– 30707, 30710, 30711, 30713, 30717, 30719, 30720, 30725, 30726, 30729–30735, 30739, 30743, 30745–30748, 30755, 30773. The lower part of the body cavity was opened and the left testis or ovary was removed, embedded in paraffin, histological sections were cut at 5 µm and stained by Harris hematoxylin followed by eosin counterstain. Histology slides are deposited at UCM.

All 19 *G. rhodogaster* males were undergoing spermiogenesis in which the seminiferous tubules were lined by sperm or groups of metamorphosing spermatids. Three males exhibited late spermiogenesis in which the germinal epithelium was reduced to a few layers of spermatogenic cells. These males (UCM 30696, 30720, 30730) were likely near the close of sperm formation. Goldberg (2006. Herpetol. Rev. 37:351) similarly reported all seven *G. semidoliatus* males collected in July from Veracruz, Mexico exhibited spermiogenesis. The smallest reproductively active *G. rhodogaster* male measured 181 mm SVL (UCM 30734).

The mean SVL of the female sample was significantly larger than that of the male sample (unpaired t-test, $t = 5.1$, $df = 34$, $p = < 0.0001$). Two stages were present in the ovarian cycle: 1) quiescent, no yolk deposition; 2) early yolk deposition (basophilic vitellogenic granules in ooplasm). Seventy-six percent (13/17) of females exhibited early yolk deposition. This large number of females in the same stage of the ovarian cycle (early vitellogenesis), from a limited time period (6 July to 4 August), suggests a high level of synchrony in the ovarian cycle of *G.* rhodogaster. The smallest reproductively active female (early yolk deposition) measured 220 mm SVL (UCM 30706).

I thank Christy McCain (UCM) for permission to examine *G. rhodogaster* and Emily M. Braker (UCM) for facilitating the loan.

STEPHEN R. GOLDBERG, Whittier College, Department of Biology, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

***HETERODON KENNERLYI* (Mexican Hog-nosed Snake). MAXIMUM SIZE.** The maximum size reported for *Heterodon kennerlyi* for the state of New Mexico is 760 mm total length (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. University of New Mexico Press, Albuquerque. 431 pp.). On 10 June 2015 at 1005 h, a large female *H. kennerlyi* was encountered moving along an access road along the eastern periphery of the main dune field outside of White Sands National Monument proper, Otero Co., New Mexico, USA. The snake measured 705 mm SVL, 795 mm total length and weighed 301 g. This record exceeds the maximum recorded total length for the species in New Mexico

by 35 mm (5%). The snake was released at point of capture the following day.

JUSTIN HOBERT, Soledad Surveys and Science, Las Cruces, New Mexico 88011, USA; e-mail: snakeyman@gmail.com.

***HETERODON NASICUS* (Plains Hog-nosed Snake). DIET.** *Heterodon nasicus* uses both olfactory and visual cues to find its prey: toads, reptiles, smaller snakes, and small turtles and their eggs (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, Washington, D.C. 668 pp.). On 6 June 2000, a *H. nasicus* was observed on a roadside in the Pawnee National Grassland (Weld Co, Colorado, USA; 40.6824°N, 104.4859°W, WGS 84; elev. 1557 m). The snake had seized a *Phrynosoma hernandesi* (Greater Short-Horned Lizard) by the lizard's head (Fig. 1). In response to the attack, the lizard inflated its lungs. *H. nasicus* have large and flexible mouths with rear fangs and are mildly venomous, adaptations that facilitate eating inflated toads. However, the lizard managed to briefly free itself from its head-first position in the snake's mouth. The snake quickly repositioned itself and seized the torso directly behind the prey's right foreleg. The lizard remained inflated. With the lizard secured in this position, the snake moved (2.5 m) from the roadside into vegetation where it eventually repositioned the unresponsive lizard before ingesting it. Elapsed time was approximately 3.25 h. Ernst and Ernst (*op. cit.*) report "*Phrynosoma* sp." as a prey item of *H. nasicus*. To our knowledge, this is the first photograph-verified record of a *P. hernandesi* as confirmed prey in the diet of *H. nasicus*.

FIG. 1. *Heterodon nasicus* predation of *Phrynosoma hernandesi* in Colorado, USA.

MARTIN,** Natural Resource Ecology Laboratory, Colorado State University, 1499 Campus Delivery, Fort Collins Colorado, USA; **ROD D. ADAMS,** Front Range Community College, 4616 S Shields St., Fort Collins, Colorado, USA.

***LAMPROPELTIS HOLBROOKI* (Speckled Kingsnake). DIET / OPHIOPHAGY.** Previous diet studies on *Lampropeltis holbrooki* have found that they prey on a multitude of animals including venomous and non-venomous snakes, lizards, turtles, reptile eggs, nestling and fledgling birds, mice and rats (Ernst and Barbour 1989. Snakes of Eastern North America. George Mason University Press, Fairfax, Virginia. 282 pp.). Herein, we report on the first incidence of *L. holbrooki* feeding on *Virginia striatula* (Rough Earthsnake).

FIG. 1. Posterior half of *Virginia striatula* extending from the body of *Lampropeltis holbrooki*.

On 17 April 2015 we collected a road-killed female *Lampropeltis holbrooki* (SVL = 696 mm; tail length = 96 mm) 4.0 km N of Ravenden Springs on Upper Jane's Creek Road, Randolph Co., Arkansas, USA (36.33362°N, 91.23387°W, NAD 83; elev. 169 m). The stomach had been split open, revealing the tail of a partially digested *V. striatula* (Fig. 1; SVL = 250 mm; tail length = 42 mm). This record is not surprising, given that *L. holbrooki* are known to feed on *Virginia valeriae* (Smooth Earthsnake; Viosca 1918. *In* Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana University Press, Baton Rouge, Louisiana. 300 pp.) and that both *Lampropeltis calligaster rhombomaculata* (Mole Kingsnake) and *L. elapsoides* (Scarlet Kingsnake) have been known to prey on *V. striatula* (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 600 pp.). Both snakes were deposited in the Arkansas State University Museum of Zoology Herpetological Collection (ASUMZ 33346, 33347, respectively), Arkansas State University, Arkansas, USA.

JOHN D. KONVALINA (e-mail: john.konvalin@smail.astate.edu), **STANLEY E. TRAUTH** (e-mail: strauth@astate.edu), **CHRISTOPHER S. THIGPEN**, and **SAMUEL A. SCHRATZ**, Department of Biological Sciences, Arkansas State University P.O. Box 599, State University, Arkansas 72467, USA.

***LAMPROPELTIS ZONATA* (California Mountain Kingsnake). PREDATION.** Predation of *Lampropeltis zonata* in the wild has rarely been observed, with other species of snakes (*L. californiae, Diadophis punctatus*) as the only documented predators (Staub et al. 2006. Herpetol. Rev. 37:231–232). On 26 April 2015, at 1150 h, RC and AC observed a *Urocyon littoralis* (Island Fox) that had made visual contact with an adult *L. zonata* (Total Length ca. 75 cm; LACM PC 1869) on a trail on Santa Catalina Island, Los Angeles Co., California, USA (33.32193611°N, 118.343344°W, WGS 84; 227 m elev.). As the fox approached the slow-moving snake, the snake stopped (Fig. 1A). The fox made two quick moves toward the snake's head, and then bit down on the snake's body (Fig. 1B), shook it violently, and ran off into nearby brush. The fox proceeded to consume the snake, rested for an hour, and then moved out of view.

Studies of Island Fox diet suggest that snakes are rarely taken (Collins 1980. *In* Proceedings of the Second Conference on Scientific Research in the National Parks, pp. 152–164. USDI National Park Service, Washington, DC; J. King, pers. comm.). For example, an analysis of > 2900 fox scats collected from all six of the California Channel Islands revealed no snake remains (Cypher et al. 2011. Resource Exploitation by Island Foxes: Implications for Conservation. California Department of Fish and Game, Nongame

PHOTOS BY RICHARD CAZARES

FIG. 1. A) Island Fox at first encounter with an adult *Lampropeltis zonata* on Santa Catalina Island, Los Angeles Co., California. B) After an initial approach, the fox bit the snake at midbody and carried it off into nearby brush, where it was consumed.

Wildlife Program Report No. 2011-01, San Diego, California. 25 pp.). We are aware of only one other report of snake predation by Island Foxes. Coonan et al. (2010. Decline and Recovery of the Island Fox: a Case Study for Population Recovery. Cambridge University Press, New York. 232 pp.) published a photo of a fox that had captured an adult *Coluber constrictor* near Scorpion Ranch, Santa Cruz Island (Santa Barbara Co., California) in July 2006 (C. Schwemm, pers. comm.; www1.islandfox.org/2006/08/what-do-island-foxes-eat.html).

This observation also represents an important locality record for *L. zonata*, which is rare or absent from islands off California. Holder (1910. The Channel Islands of California: A Book for the Angler, Sportsman, and Tourist. Hodder and Stoughton, London. 397 pp.) observed a "coral snake" on Santa Catalina Island, clearly a first reference to the occurrence of *L. zonata* on any of the California Channel Islands. Backlin et al. (2005. Baseline Biodiversity Survey for Santa Catalina Island: Herpetofauna and Ants with Remarks on Small Mammals and Others. USGS Western Ecological Research Center Final Report, San Diego, California. 45 pp.) published a photo of a *L. zonata* found in 1999 at Black Jack Campground, ca. 9 km by air NW of the new locality. Because Backlin et al. (2005, *op. cit.*) did not record *L. zonata* during their extensive trapping surveys over a 34-month period, they questioned whether that species naturally occurs on the island. However, given the antiquity of Holder's (1910) report, together with our new record from a wilderness area, we regard *L. zonata* as a natural inhabitant of Santa Catalina Island. The island localities are roughly 60 km SE overwater from the nearest vouchered locality of *L. zonata* on the mainland (SDNHM 24269; 2 miles S of Irvine, Orange Co., California), although Hubbs (2004. Mountain Kings: A Collective Natural History of California, Sonoran, Durango and Queretaro Mountain Kingsnakes. Tricolor Books, Tempe, Arizona. 319 pp.) noted an unconfirmed sight record for the Palos Verdes Hills, Los Angeles Co., roughly 40 km N of the Santa Catalina Island localities. This report confirms the presence of *L. zonata* on Santa Catalina Island. This species remains unknown from any other California islands.

In addition to digital images of the snake-fox interaction, a video file is available as LACM PC 1871. We thank Paul Collins, Julie King, and Cathy Schwemm for helpful discussion, information, and references.

***LEPTODEIRA ANNULATA* (Banded Cat-eyed Snake). REPRODUCTION / MATING AGGREGATION.** Aggregative behavior constitutes one of the unambiguous cases of social behavior in snakes, and research increasingly supports the complexity of snake social systems (Greene et al. 2002. *In* Schuett et al. [eds.], Biology of the Pitvipers, pp. 179–205. Eagle Mountain Publishing, Eagle Mountain, Utah; Clark et al. 2012. Biol. Lett. 8:523–525). In fact, records of snake aggregations are widespread (e.g., Gregory et al. 1987. *In* Seigel et al. [eds], Snakes—Ecology and Evolutionary Biology, pp. 366–395. Macmillan, New York; Ford and Burghardt 1993. *In* Seigel and Collins [eds], Snakes—Ecology and Behavior, pp. 117–164. McGraw-Hill, New York), and many tend to be related to reproductive activities (Graves and Duvall 1995. Herpetol. Monogr. 9:102–119; Rivas and Burghardt 2005. J. Comp. Psychol. 119:447–454).

Leptodeira annulata is a nocturnal and semi-arboreal snake widely distributed in the Neotropics that feeds mainly on anurans. Although its ecology has been relatively well studied in South America (Vitt 1996. Herpetol. Nat. Hist. 4:69–76; Ávila and Morais 2007. Herpetol. Rev. 38:278–280; Mesquita et al. 2013. Pap. Avul. Zool. 53:99–113), little is known about its mating behavior (Carvalho-Neto et al. 2007. Herpetol. Rev. 38:89). Herein, we expand the understanding on the reproductive behavior of *L. annulata* through the record of breeding aggregation for this species.

On 1 May 2011 at 1030 h, five *L. annulata* were collected at Mocozal (3.9815°S, 38.7284°W, WGS 84; elev. 138 m), Maranguape municipality, Ceará state, northeastern Brazil, and deposited in the scientific collection Coleção Herpetológica da Universidade Federal do Ceará (CHUFC 3606–3610). The snakes, a female (SVL = 61.5 cm) and four males (SVLs = 56.1, 52.5, 51.5, and 47.8 cm), were found tangled together at ground level. The close arrangement among the individuals and the male-biased sex ratio suggest that this was a mating aggregation. Our observation provides evidence that *L. annulata* forms breeding balls, and despite its primarily arboreal and nocturnal habits, may copulate on the ground during daylight.

We thank Lunardo Martins de Albuquerque for assistance in sampling.

DANIEL CUNHA PASSOS, Universidade do Estado do Rio de Janeiro, Pavilhão Haroldo Lisboa da Cunha, Sala 224, Rua São Francisco Xavier, 524,

***LYTORHYNCHUS DIADEMA* (Awl-headed Snake). DEFENSIVE BEHAVIOR.** At 2330 h, SDB collected a female *Lytorhynchus diadema* (total length = 333 mm) crossing the road ~21.7 km N on N-1 from the intersection of P-1600 and N-1 just outside of Tan-Tan, Morocco (28.562037°N, 10.907357°W, WGS 84; elev. ~318 m, T_a = 17.8°C). The snake was photographed in life the following morning, and preserved (CM 55251). During the initial encounter, this individual presented a cobra-like display, flattening its neck and raising its head and body about 5 cm off the ground. The entire display lasted 15–20 sec. This behavior has not been reported in this species from northwestern Africa (PG, JMP, L. García-Cardenete, and R. León, pers. comm.; Šmíd 2010. Herpetol. Notes 3:329–332), but it is apparently not rare in Israel where it can be elicited by touching the snake on the base of the tail (Fig. 1).

Juvenile and adult sand snakes (*Ragerhis moilensis)* and cobras (*Naja haje*), which are sympatric and syntopic with *Lytorhynchus* throughout much of its range, commonly exhibit neck-spreading defensive behavior (Geniez et al. 2004. The Amphibians and Reptiles of the Western Sahara. Chimaira Buchhandelsgesellschaft mbH, Frankfurt am Main, Germany. 229 pp.; Sindaco et al. 2013. The Reptiles of the Western Palearctic. 2. Monografie della Societas Herpetologica Italica – II. Edizioni Belvedere, Latina, Italy. 543 pp.) and the display of *Lytorhynchus* might be an example of mimicry. The blotched pattern typical of *L. diadema* and *R. moilensis* is also seen in sympatric vipers: *Bitis, Cerastes, Daboia, Echis, Macrovipera,* and *Pseudocerastes.* If potential predators generalize blotched patterns of venomous snakes broadly, *L. diadema* may be incorporating features of both cobra neck-spreading and viper pattern similarity as an anti-predator defense. Alternatively, both the pattern and the behavior of *L. diadema* may be pleisiomorphic, developmentally-canalized characters (Pough 1988. *In* Gans and Huey [eds], Biology of the Reptilia, Vol. 16, Ecology B, Defense and Life History, pp.153–234. Alan R. Liss, New York; Pough 1988. Am. Nat. 131:S67–S102).

We thank F. H. Pough, who generously read a preliminary version of this manuscript, suggested organizational changes, and proffered alternative possibilities for our initial observations.

BUSACK, North Carolina Museum of Natural Sciences, Raleigh, North Carolina 27601, USA (e-mail: sbusack348@aol.com); **JAIM SIVAN**, Department of Life Sciences, Achva Academic College, Achva, Israel (e-mail: jaimsivan@gmail.com); **PHILIPPE GENIEZ**, CEFE UMR 5175, CNRS - Université de Montpellier - Université Paul-Valéry Montpellier - EPHE, 1919, route de Mende 34 293 Montpellier cedex 5, France (e-mail: philippe.geniez@cefe.cnrs.fr); **JUAN M. PLEGUEZUELOS**, Departamento de Zoología, Facultad de Ciencias, Universidad de Granada, E-18071, Granada, Spain.

***MICRURUS DUMERILII* (Dumeril's Coralsnake). MAXIMUM SIZE.** The maximum total length reported for *Micrurus dumerilii* is 948 mm (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Cornell University Press, Comstock Publishing Associates, Ithaca, New York. 870 pp.). At 1015 h on 26 Febraury 2014, during a diurnal visual encounter transect for herpetofauna, we captured a female *M. dumerilii* (SVL = 858 mm, tail length = 96 mm) in Predio La Vega, vereda Mirabel, municipality Betulia, Santander, Colombia (7.030917°N, 73.378778°W, WGS 84; 198 m elev.). At 954 mm total length, this specimen is the longest known *M. dumerilii*. The snake was collected and deposited in the Colección Herpetológica at the Universidad Industrial de Santander, Colombia (UIS-R-2711).

ELSON MENESES-PELAYO (e-mail: bioelsonp@gmail.com) and **JOSÉ RANCES CAICEDO-PORTILLA**, Escuela de Biología, Universidad Industrial de Santander, Bucaramanga, Colombia.

***NERODIA ERYTHROGASTER* (Plain-bellied Watersnake). PREDATION.** *Nerodia erythrogaster* is found throughout much of the eastern and central United States. Surprisingly few species have been recorded as predators of this widespread snake (Gibbons and Dorcas 2004. North American Watersnakes. University of Oklahoma Press, Norman. 438 pp.). For example, although *N. erythrogaster* is highly aquatic, to our knowledge there is only one documented observation of a fish as a predator. In 1984, a small *N. erythrogaster* in Tarrant Co., Texas was reported within a *Micropterus salmoides* (Largemouth Bass; Parmley and Mulford 1985. Texas J. Sci. 37:389). However, no museum records are associated with the observation.

On 3 April 2015, several *M. salmoides* were captured in a private fishing pond in Edgefield Co., South Carolina (33.635976°N,

FIG. 1. Juvenile *Nerodia erythrogaster* found within a *Micropterus salmoides* (Largemouth Bass) captured in South Carolina. The snake was discovered and cut in pieces in the course of filleting the fish.

81.889167°W; WGS 84). Upon cleaning one of the fish, RA noticed a dead but largely intact juvenile *N. erythrogaster* inside (Fig. 1), suggesting that the snake had been consumed in a recent predation event. The current observation is separated from the only other known fish predation record by over 30 years and 1000 km. Photographic vouchers were deposited in the Auburn University Museum of Natural History (AHAP-D 1092a, b).

RON ARBAUGH, Aiken, South Carolina, USA; **TRAVIS ARBAUGH**, Lexington, South Carolina, USA; **DAVID A. STEEN**, Department of Biological Sciences, Auburn University, 1090 South Donahue Drive, Auburn, Alabama, USA (e-mail: davidasteen@gmail.com).

***NERODIA SIPEDON PLEURALIS* (Midland Watersnake). ACANTHOCEPHALAN PARASITE.** Although much is known about the helminth parasites of *Nerodia sipedon*, little is known of those of *N. s. pleuralis* (Ernst and Ernst 2006. SSAR Herpetol. Circ. 34:1–86). In addition, we are not aware of any acanthocephalan (spiny-headed worm) parasite reported from *N. s. pleuralis*. Here, we report a new host and distributional record for an acanthocephalan from a *N. s. pleuralis* in Arkansas.

Nine juvenile and adult *N. s. pleuralis* (SVLs = 162–775 mm) were collected between April 2010 and July 2014 from Fulton (N = 1), Franklin (N = 1), Independence (N = 5), Marion (N = 1) and Montgomery (N = 1) counties, Arkansas, USA. They were euthanized with an intraperitoneal injection of sodium pentobarbital (Nembutal®) and a mid-ventral incision was made to expose the visceral contents. A single male acanthocephalan was recovered from the small intestine, placed overnight in tap water, fixed in 70% ethanol, stained with acetocarmine and mounted in Damar balsam, and identified by MAB. A voucher specimen (HWML 75378) was deposited in the Harold W. Manter Laboratory (HWML) of Parasitology, University of Nebraska-Lincoln. A host voucher specimen was deposited in the Arkansas State University Museum (ASUMZ) Herpetological Collection, State University, Arkansas.

One of 9 (11%) *N. s. pleuralis* collected on 5 March 2014 from Mill Creek at Spring Mill, Independence Co. (35.825°N, 91.725°W; WGS 84) was found to be infected with a single male acanthocephalan that fit the description of *Pomphorhynchus bulbocolli* Linkins in Van Cleave, 1919. This acanthocephalan has been previously reported widely from North America in over 80 freshwater fishes (Amin 1987. J. Parasitol. 73:278–289; Hoffman 1999. Parasites of North American Freshwater Fishes. 2nd ed. Comstock Publishing Associates, Ithaca, New York. 539 pp.). Intermediate hosts of *P. bulbocolli* are the amphipods, *Gammarus pseudolimnaeus* and *Hyalella azteca* (Muzzall 1982. J. Helminthol. Soc. Washington 49:289–294; Barger and Nickol 1998. J. Parasitol. 84:534–537). The presence of *P. bulbocolli* in this snake is considered to be an artifact of a piscivorous diet and the host should be considered accidental. However, this is the first time this acanthocephalan has been reported in *N. sipedon*.

We thank the Arkansas Game and Fish Commission for a Scientific Collecting Permit issued to CTM, and S. L. Gardner (HWML) and S. E. Trauth (ASUMZ) for expert curatorial assistance.

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); **MICHAEL A. BARGER,** Department of Natural Science, Peru State College, Peru, Nebraska 68421, USA (e-mail: mbarger@peru.edu); **HENRY W. ROBISON**, 9717 Wild Mountain Drive, Sherwood, Arkansas 72120, USA (e-mail: hwrobison@yahoo.com).

***OXYBELIS AENEUS* (Brown Vinesnake). DIET.** *Oxybelis aeneus* is a long, slender, arboreal snake that is widely distributed from Arizona, USA, to southeastern Brazil (Stebbins 1954. Amphibians and Reptiles of Western North America. McGraw-Hill, New York, USA. 536 pp.). Its diet includes a wide range of vertebrates, including amphibians, arboreal mammals, small rodents, small birds, fish, and primarily lizards (Henderson 1982. Amphibia-Reptilia 3:71–80; Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. University of Chicago Press, Illinois. 934 pp.; Hetherington 2006. Herpetol. Rev. 37:94–95).

At 1119 h on 19 May 2015, at Pontal da Santa Cruz (7.21051111°S, 39.7335444°W, WGS 84; 730 m elev.), located at Chapada do Araripe municipality of Santana do Cariri, Ceará state, Brazil, an adult male *O. aeneus* (SVL = 917 mm; Tail length = 549 mm; 91 g) was sighted in a tree ingesting an adult male *Tropidurus hispidus* (Fig. 1A; SVL = 79 mm; Tail length = 130 mm; 25.4 g) headfirst. During collection the snake regurgitated the freshly killed lizard. Both the snake and the lizard were collected and deposited at the Coleção Herpetológica da Universidade Regional do Cariri (Fig. 1B; URCA-H 11017, 11018, respectively). Despite the variety of prey types reported for diet of *O. aeneus*, to the best of our knowledge this is the first record of predation by *O. aeneus* on *T. hispidus*.

We thank Fundação Cearense de Apoio ao Desenvolvimento Científico e Tecnológico (FUNCAP) for a research fellowship to RWA (process BPI-0067-000060100/12) and for a Master fellowship to EPA; and Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) for a Master fellowship to CFS.

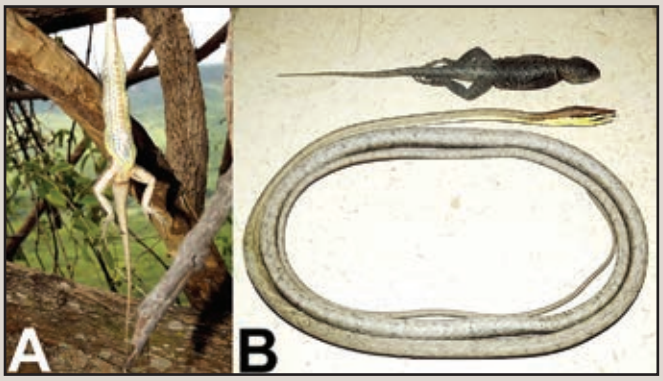

PHOTO BY H. F. OLIVEIRA

Antônio Luiz, 1161, Bairro do Pimenta, CEP 63105-100, Crato, Ceará, Brazil.

***PSAMMOPHIS SCHOKARI* (Schokari Sand Racer). ENDOPARASITE.** *Psammophis schokari* occurs throughout Israel and is widely distributed in the Middle East and northern Africa (Bar and Haimovitch 2011. A Field Guide to Reptiles and Amphibians of Israel. Pazbar Ltd., Herzilya. 245 pp.). Tomé et al. (2013. J. Parasitol. 99:883–887) reported apicomplexan parasites in *P. schokari*. In this note we add to the *P. schokari* parasite list.

The body cavity of one female *P. schokari* (SVL = 545 mm) from the Zoological Museum of Tel Aviv University (TAUM), Tel Aviv, Israel (TAUM 12177) collected May 1980 at Holon (32.0167°N, 34.7667°E; WGS 84) in the Southern Coastal Plain Region, was examined for endohelminths. One nematode was found. It was cleared in lactophenol, placed on a microscope slide, coverslipped, and studied using a compound microscope. A mature female nematode was found. The presence of unlobed pseudolabia supporting medial and externolateral teeth allowed it to be identified as *Abbreviata* sp. (Physalopteridae). Species assignment depends on male characters; although it should be noted that *A. adoisi* has been reported from lizards collected in Lebanon (Sulahian and Schacher 1968. J. Helminthol. 42:373–382). The specimen was deposited in the Harold B. Manter Helminthological Collection (HWML), University of Nebraska, Lincoln, USA as (HWML 64807).

Species of *Abbreviata* are common parasites of lizards and snakes (Baker 1987. Mem. Univ. Newfoundland, Occas. Pap. Biol. 11:1–325). The infection site typically is the stomach (Anderson 2000. Nematode Parasites of Vertebrates Their Development and Transmission, 2nd ed., CABI Publishing, Oxfordshire, UK. 650 pp.). It may have entered the body cavity through a perforation in the stomach wall during preservation of the snake. *Psammophis schokari* represents a new host record for species of *Abbreviata.*

We thank Shai Meiri (TAUM) for permission to examine *P. schokari,* Erez Maza (TAUM) for facilitating the loan, and the National Collections of Natural History at Tel Aviv University for providing the *P. schokari* to examine.

STEPHEN R. GOLDBERG, Whittier College, Department of Biology, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **CHARLES R. BURSEY**, Pennsylvania State University, Department of Biology, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail:cxb13@psu.edu).

***PSEUSTES SHROPSHIREI* (Shropshire's Puffing Snake). DIET.** The genus *Pseustes* includes diurnal, nocturnal, terrestrial, and semi-arboreal snakes (Martins and Oliveira 1998. Herpetol. Nat. Hist. 6:78–150). The diet of *P. shropshirei* is poorly known, consisting only of the seeds from an undetermined plant, and two white brittle-shelled eggs with partially developed avian embryos (Cisneros-Heredia 2005. Herpetol. Rev. 36:327) recovered from a specimen from Ecuador. Here, we present the first record of predation of *P. shropshirei* upon nestling birds (Columbidae: *Zenaida*).

On 30 July 2014 at 1430 h, a juvenile male *P. shropshirei* (SVL = 900 mm; TL = 360 mm; 246 g) was found at the edge of a dirt road in Vereda Cadenales, municipality of Norcasia, department of Caldas, Colombia (5.60759°N, 74.90998°W, WGS 84; elev. 874 m). The snake, which had been killed by a local farmer, was collected and deposited in the herpetological collection of the Museo de Historia Natural de la Universidad de Caldas (MHN-UCa 252). The specimen appeared to contain a large food item, and dissection revealed two nestling *Zenaida* sp. (Fig. 1). The first prey item (Length = 6.5 cm; 27.1 g) was consumed headfirst, and the second prey (Length = 7.2 cm; 24 g) was consumed legs-first. The birds appeared to have been recently consumed and were probably captured alive.

This record provides new knowledge about the feeding habits of *P. shropshirei*, suggesting that like other species in the genus, it preys upon eggs and nestlings of various bird species (Tweit 1996. The Birds of North America. Cornell Lab of Ornithology, Ithaca, New York. 20 pp.; Stake et al. 2005. J. Herpetol. 39:215–222).

FIG. 1. Dead male *Pseustes shropshirei* from the department of Caldas, Colombia that had consumed two nestlings of *Zenaida* sp.

We thank ISAGEN (contract 47/180) for partially funding fieldwork associated with this note.

***SIBON LONGIFRENIS* (Drab Snail-eater). AGGREGATION.** Aggregation is a behavior known in many species of snakes throughout the world. Aggregation has been observed mainly in species from temperate and subtropical zones and has been attributed to mating and overwintering behavior. However, few cases have been observed in tropical species. Here, we report the first aggregation of *S. longifrenis* in tropical rain forest habitat in Costa Rica.

On 27 July, during a field trip in Quebrada González sector of Braulio Carrillo National Park (10.16280°N, 83.94030°W, WGS 84; 535 m elev.), at ca. 0032 h, we observed an aggregation of six *S. longifrenis* actively moving in an understory palm tree, ca. 2–3 m above the ground (Fig. 1). The aggregation consisted of five males (SVLs = 36–58.5 cm) and one non-gravid female (SVL = 56 cm). Since the observation took place at night in tropical rain forest habitat and the individuals were actively moving in a palm tree,

FIG. 1. Aggregation of *Sibon longifrenis* on a palm tree in Braulio Carrillo National Park, Costa Rica. Four of six individuals can be seen.

it is likely that the aggregation was related to mating, rather than thermoregulation. This conclusion is further supported by the highly skewed sex ratio of the group.

***SONORA SEMIANNULATA* (Western Groundsnake). PREDATION.** *Sonora semiannulata* is a common snake found in the central and southwestern U.S. and northern Mexico (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 668 pp.). They have a range of documented predators, including lizards, snakes, birds, and mammals (Ernst and Ernst, *op. cit.*). On 01 November 2014, 11.5 km SE of Valentine, Jeff Davis Co., Texas, USA (30.52166°N, 104.40198°W, WGS 84), we collected at least two identifiable *S. semiannulata* impaled on barbed wire (Fig. 1) at a larder of *Larius ludovicianus* (Loggerhead Shrike). To our knowledge this is the first documented instance of this bird predating *S. semiannulata*

PHOTO BY CRYSTAL KELEHEAR

***STORERIA DEKAYI* (Dekay's Brownsnake). POPULATION SIZE, DENSITY, AND BIOMASS.** *Storeria dekayi* is a small North American natricine snake that is relatively common in a wide variety of habitats, including those associated with human habitation (Christman 1982. Cat. Amer. Amphib. Rept. [461]:1–2). Despite the ubiquity of *S. dekayi*, population size and density estimates for the species are few. In suitable habitat, with a plentiful supply of shelter and prey (e.g., slugs and earthworms), population of *S. dekayi* can be quite large (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Press. Washington, DC. xi + 668 pp). The purpose of this note is to report multi-year estimates of population size (N), density (N/area of sampled habitat), and biomass (N × average mass of all marked snakes) at a 0.5-ha urban site in Erie, Pennsylvania, USA.

During the active seasons (March–October) of 2012–2014, I used artificial cover objects along a vegetated slope to study a population of *S. dekayi* (Gray 2014. J. North Amer. Herpetol. 2014:28–39). The Schumacher-Eschmeyer mark-recapture method was used to estimate population size (Ricker 1975. Computation and Interpretation of Biological Statistics of Fish Populations. Bull. Fish. Res. Board Canada 191:1–382). For the population size estimates, each sample consisted of a weekly sampling period up until the first neonate(s) were observed. The population size and density at the site during 2012 were estimated as 130 ± 35 individuals and 260 *S. dekayi* / ha, respectively (Gray 2014, *op. cit.*). Total biomass of *S. dekayi* during 2012 was estimated to be 855 g.

During 2013, thirty-seven adult male (mean ± 95% C.I., SVL = 214.2 ± 6.7 mm), 24 adult female (SVL = 267.5 ± 12.7 mm), 37 juvenile male (SVL = 149.4 ± 5.7 mm), and 52 juvenile female (SVL = 163.8 ± 8.5 mm) *S. dekayi* were marked. During 2013 the first neonates were observed 6 August. Population size was estimated as 195 ± 53 individuals, resulting in a population density of 390 *S. dekayi*/ha. Total biomass during 2013 was estimated to be 975 g. During 2014, fifteen adult male (SVL = 218.1 ± 11.4 mm), 16 adult female (SVL = 277.9 ± 11.2 mm), 13 juvenile male (SVL = 150.0 ± 9.6 mm), and 11 juvenile female (SVL = 170.2 ± 18.0 mm) *S. dekayi* were marked. During 2014 the first neonates were observed 18 August. Population size during 2014 was estimated as 77 ± 16 individuals, resulting in a population density of 154 *S. dekayi*/ha. Total biomass of *S. dekayi* during 2014 was estimated to be 485 g.

Populations of *S. dekayi* vary considerably in size depending on numerous factors, including the amount of suitable habitat, abundance of prey, intensity of predation, and female fecundity. For instance, estimated population sizes and densities from select studies range from 152–4200 individuals and 14–300/ha, respectively (Freedman and Catling 1978. Can. Field Nat. 92:167–173; Mitchell 1995. Catesbeiana 15:15–22; Ernst 2003. Herpetol. Bull. 86:10–18). Populations of *S. dekayi* at sites noted by Ernst have since been extirpated (Ernst 2003, *op. cit.*). The apparent decline of *S. dekayi* at my Erie County site may have been due

to the harsh winter of 2013–2014. Average air temperature in Erie, Pennsylvania during 1 November 2013 through 31 March 2014 was 5.2°F below average, with March 2014 being the 7th coldest (mean temp 28.1°F) on record (National Oceanic and Atmospheric Administration, http://www.weather.gov/climate/. Accessed 11 January 2015). Furthermore, during 2014 the first *S. dekayi* were observed 19 April, compared to 21 March and 30 March during 2012 and 2013, respectively. Such an extended winter may have caused substantial mortality during hibernation.

I offer my thanks to Jim Harding and Walter Meshaka, Jr. for comments and suggestions regarding the manuscript.

***TACHYMENIS PERUVIANA*. DIET.** Snakes in the genus *Tachymenis* are known to feed mainly on amphibians and lizards (Walker 1945. Publ. Mus. Comp. Zool. 55:1–55; Greene and Jaksi 1992. Rev. Chil. Hist. Nat. 65:485–493). On 2 January 2014 we encountered a dead and dried-out juvenile *T. peruviana* (SVL = 144 mm, Tail Length = 44 mm) that had fed on a male *Liolaemus aparicioi* (SVL = 44 mm; swallowed headfirst), an endemic lizard species of La Paz valley, Bolivia (Ocampo et al. 2012. Herpetologica 68:410–417). The specimen was found at Taypichulo (16.64°S, 68.05°W, WGS 84; elev. 3002 m), a locality on the eastern bank of the Rio La Paz. The snake's midbody was distended, and its ventral region was slightly decomposed and opened with forelimbs and abdomen of the lizard exposed (Fig. 1). Although it is common to find positive correlations between prey and snake size, juvenile snakes sometimes eat relatively large prey (Sazima and Martins 1990. Memórias do Instituto Butantan 52:73–79), as in this case. Sazima and Martins suggest that eating large prey entails increased handling time as well as time and energy invested in digestion, while it may increase the risk of predation, or death by internal injuries or asphyxia, as may have been the case here. This is the first report of a diet item for juvenile *T. peruviana* in the field. The specimen (CBF 3913) was deposited as a voucher in Herpetology Field of Colección Boliviana de Fauna.

We thank Jorge Salazar Bravo, Patrick Gregory, and John D. Willson for their contributions on the manuscript.

***TANTILLA CORONATA* (Southeastern Crowned Snake). COLORATION.** On 5 July 2008, in Okaloosa Co., Florida, USA, an adult (total length = 20 cm) amelanistic *Tantilla coronata* was found under a piece of plywood near the edge of a mixed pine/hardwood forested area with no recent history of fire. The snake was photographed (Fig. 1) and immediately released where it was found. This is apparently the first documented amelanistic *T. coronata*. Although it might be difficult to get a good sense of how frequently this coloration occurs in this generally seldom seen species, a study involving 1640 captures of *T. coronata* over 56 years (Todd et al. 2008. Copeia 2008:388–394.) included no amelanistic individuals (B. Todd, pers. comm.).

***THAMNODYNASTES STRIGATUS* (Corredeira). DIET.** *Thamanodynastes strigatus* is a semi-arboreal opportunistic predator (Bernarde et al. 2000. Bol. Mus. Nac. Zool. 428:1–8; Franco and Ferreira 2002. Phyllomedusa 1:57–74) with a wide geographic distribution in Paraguay, Uruguay, Argentina, and southern and southeastern Brazil (Bernarde et al. 2000, *op. cit.*; Condez et al. 2009. Biot. Neotrop. 9:157–185). Its diet is composed mainly of anurans, but it has also been recorded preying on fish, rodents, and small reptiles (Bernarde et al. 2000. Rev. Bras. Biol. 60:695–699; Marques et al. 2001. Serpentes da Mata Atlântica. Guia Ilustrado. Holos Editora, Ribeirão Preto. 184 pp.). Among the fish comprising part of its diet, only small and inoffensive fish as some poeciliid species have been recorded (Bernarde et al. 2000, *op. cit.*; Ruffato et al. 2003. Phyllomedusa 2:27–34). In 09 April 2015 we received a dead adult female *T. strigatus* (SVL = 40.0 cm; Tail length = 12.0 cm) from Condomínio Estância Zaúna (23.396083°S, 51.835916°W, WGS 84; 468 m elev.), a settlement in the municipality of Maringá, Paraná state, Brazil. We dissected the specimen and recorded one *Hoplias* aff. *malabaricus* (Trahira; SVL ca. 16.0 cm) in the stomach of snake (Fig. 1). *H. malabaricus* is a carnivorous and aggressive fish and is considered an important aquatic predator (Luz et al. 2000. Act. Sci.

FIG. 1. *Hoplias* aff. *malabaricus* (Trahira) consumed by a *Thamnodynastes strigatus* in Brazil.

22:465–469). The present record expands the known diet of *T. strigatus* and further demonstrates the dietary plasticity of this species.

***THAMNOPHIS BRACHYSTOMA* (Short-headed Gartersnake). POPULATION SIZE, DENSITY, AND BIOMASS.** *Thamnophis brachystoma* is endemic to the Allegheny High Plateau of northwestern Pennsylvania and southwestern New York. *Thamnophis brachystoma* is reportedly extremely abundant within its limited geographic range (Conant 1950. Bull. Chicago Acad. Sci. 9[4]:71–77; Hulse et al. 2001. Amphibians and Reptiles of Pennsylvania and the Northeast. Cornell University Press, Ithaca, New York. i–xi + 419 pp.), especially in localized habitat (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. University of Oklahoma Press, Norman. i–xx + 332 pp). Despite these reports of abundance, quantitative estimates such as population size and density of *T. brachystoma* are sparse (Asplund 1963. Herpetologica 19:128–132; Engelder 1988. A study of the short-headed garter snake, *Thamnophis brachystoma* in New York State. Unpubl. Master of Science Dissertation, St. Bonaventure University, New York. 72 pp.). Herein we provide estimates of population size, density, and biomass for two urban *T. brachystoma* populations in Erie, Pennsylvania, USA.

During April–August 2011, we studied two urban *T. brachystoma* populations. At both sites we used artificial cover objects and existing natural cover (e.g., rocks) to sample for snakes. At site 1, Shannon Road (42.12440°N, 80.00000°W; WGS 84) we sampled ca. 3.6 ha of old field habitat. At site 2, McClelland Park (42.12960°N 80.01820°W; WGS 84) we sampled ca. 4.8 ha of old field habitat. Both sites are insular and are surrounded primarily by residential neighborhoods. We used the Schumacher-Eschmeyer mark-recapture method (Ricker 1975. Computation and Interpretation of Biological Statistics of Fish Populations. Bull. Fish. Res. Board Canada 191:1–382) to estimate population size (N). For the population estimates, each sample consisted of a weekly sampling period up until the observation of the first neonate(s) or post-partum female. Density (N/area of sampled habitat) and total biomass (N x average mass of all marked snakes) was also calculated.

At the Shannon Road site, 5 juvenile male (mean ± 95% C.I. SVL = 214.2 ± 4.8 mm; mass 6.1 ± 0.4 g), 8 juvenile female (SVL = 228.6 ± 22.5 mm; mass 6.7 ± 1.2 g), 18 adult male (SVL = 273.6 ± 16.9 mm; mass 12.5 ± 2.3 g), and 25 adult female (SVL 310.8 ± 14.9 mm; mass 21.7 ± 4.0 g) *T. brachystoma* were marked. Population size was estimated to be 93 (95% C.I. = 54–132) *T. brachystoma*; population density was estimated to be 26 snakes/ha. Total biomass of *T. brachystoma* at the Shannon Road site was estimated to be 1.42 kg. At the McClelland Park site, 28 juvenile male (SVL = 190.9 ± 6.4 mm; mass 4.9 ± 0.4 g), 35 juvenile female (SVL = 205.3 ± 8.2 mm; mass 6.1 ± 0.6 g), 12 adult male (SVL = 273.4 ± 18.6 mm; mass 12.9 ± 2.6 g), and 19 adult female (SVL 322.0 ± 23.1 mm; mass 26.4 ± 6.7 g) *T. brachystoma* were marked. Population size was estimated to be 161 (95% C.I. = 125–197) *T. brachystoma*; population density was estimated to be 34 snakes/ha. Total biomass of *T. brachystoma* at the McClelland Park site was estimated to be 1.72 kg.

Both of the Erie County sites studied by us were female-biased in both the juvenile and adult age classes. Engelder (*op. cit.*) reported that four populations in New York were female-biased, with females comprising 54.8–71.4% of marked snakes. Asplund (*op. cit.*) estimated two Pennsylvania *T. brachystoma* populations to be between 555–1290 and 218–418 snakes, respectively. By contrast, Engelder (*op. cit.*) estimated a population at Horseheads, New York to average 33 (95% C.I. 17–49) *T. brachystoma*; estimated density for this same population was 20 snakes/ha. To our knowledge, site-specific biomass estimates of *T. brachystoma* have not been reported previously.

We thank the City of Erie and Pennsylvania State University, the Behrend College for access to the study sites, and Raymond Novotny and George Pisani for suggestions regarding the manuscript.

MARK LETHABY (e-mail: mlethaby@verizon.net) and **BRIAN S. GRAY** (e-mail: brachystoma@hotmail.com), Natural History Museum at the Tom Ridge Environmental Center, 301 Peninsula Drive, Erie, Pennsylvania 16505, USA.

***THAMNOPHIS EQUES* (Mexican Gartersnake). MAXIMUM SIZE.** Data on size of *Thamnophis eques* from the southern portion of their range are sparse. Two Mexican populations have been studied; one at Tecocomulco, Hidalgo, where the maximum reported SVL is 68 cm (Macias 1984. Universidad Nacional Autónoma de México. 67 pp.) and one in the Valley of Toluca (Manjarrez 1998. J. Herpetol. 32:464–468) where maximum reported SVL is 63.5 cm. Here we report a female *T. eques* captured by Victor Sustaita in the Canal Japón of the Lago de Xochimilco (south of Mexico City) on a morning in June 2008 that measured 91 cm SVL and 110 cm total length. To our knowledge, this is the largest *T. eques* reported from Mexican populations and is similar in size to the largest individuals reported in Arizona, USA (Total Length = 120 cm; Schwalbe and Rosen 1988. *In* Szaro et al. [tech. coords.], Management of Amphibians, Reptiles, and Small Mammals in North America, pp. 166–173. USDA Forest Service Gen. Tech. Rept. RM-166, Fort Collins, Colorado).

WE thank Ph. Fernando Arana of the Centro de Investigaciones Biológicas Acuícolas (CIBAC) for coordinating facilities.

***THAMNOPHIS PROXIMUS* (Western Ribbon snake). ARBOREAL BEHAVIOR.** Many species that are considered terrestrial will intermittently exploit habitats outside of their typical habitat. Even though terrestrial, *Thamnophis* spp. have been found to use arboreal basking locations, either commonly as in *T. sauritus* (Eastern Ribbonsnake) (Langford et al. 2011. Herpetol. Conserv. Biol. 6:400–409) or occasionally for thermoregulation, as in *T. sirtalis parietalis* (Red-sided Garter snake) (Shine et al. 2005. J. Therm. Biol. 30:179–185). However, there are no records to document this behavior in *T. proximus*.

On 13 March 2015 (0900 h) at Evariste Nunez Woods and Bird Sanctuary (Cameron Parish, Louisiana; 29.73857°N, 92.8373139°W, WGS 84) we observed a *T. proximus* basking ca. 1.5 m up in a young *Quercus virginiana* (Live Oak; Fig. 1) located along an edge between maintained grassland (mowed) and coastal Chenier forest; presumably, this location was ideal to thermoregulate during the spring. The surrounding Chenier had some standing water from recent precipitation events, but there was no precipitation immediately prior to the observation, which has been found to elicit arboreal basking in *T. s. parietalis* (Shine et al., *op. cit.*). Tinkle (1957. Ecology 38:69–77) found that most *T. proximus* basked in *Rubus* (blackberry) and *Typha* (cattail) mats; when shade increased with leaf out during the course of the year, individuals moved to different areas instead of moving up trees within the same habitat. However, the use of small trees for basking or foraging might be more common than represented in the literature.

FIG. 1. *Thamnophis proximus* basking in young tree in Louisiana, USA.

ZENZAL JR., Department of Biological Sciences, University of Southern Mississippi, 118 College Dr. #5018, Hattiesburg, Mississippi 39406, USA (e-mail: tjzenzal@gmail.com); **WILL SELMAN**, Rockefeller Wildlife Refuge, Louisiana Department of Wildlife and Fisheries, 5476 Grand Chenier Hwy, Grand Chenier, Louisiana 70643, USA (e-mail: wselman@wlf.la.gov).

***THAMNOPHIS SIRTALIS* (Common Gartersnake). DIET / SCAVENGING.** Occasional consumption of carrion in the wild is known in *Thamnophis sirtalis*, but interspecific competition over carrion has not been previously reported. Markezich (2010. Herpetol. Rev. 41:99–100) recently reviewed six records for scavenging in *T. sirtalis* and added two more. We provide additional reports of *T. sirtalis* scavenging, and suggest that scavenging may be a deliberate foraging strategy in this species (DeVault and Krochmal 2002. Herpetologica 58:429–436). The widespread availability of road kills is a relatively recent phenomenon from an evolutionary perspective. There are advantages to highly plastic foraging behaviors that can exploit new food resources (Krause and Burghardt 2001. Herpetol, Monogr. 15:100–123). Scavenging on roadways may be especially successful during periods of concentrated amphibian migrations that result in many road kills. Whether or not this is an advantageous survival strategy is questionable, however, as snakes are also likely to experience higher mortality when foraging along roadways.

On 3 September 1994, JBL observed a *T. sirtalis* attempting to consume a deceased *Lithobates pipiens* (Northern Leopard Frog) in the middle of a paved road in Scott Co., Minnesota, USA (ca. 5 km SW of Shakopee; 44.752951°N, 93.595761°W, WGS 84). The road-killed frog was planate, desiccated, and firmly adhered to the road surface. The snake was preoccupied due to the difficulty of removing the frog from the road, and appeared to be unaware of its immediate surroundings. No attempt to flee was made upon approach and the snake was relocated to a roadside ditch, but quickly returned and resumed its effort to dislodge the frog. JBL observed another *T. sirtalis* attempting to consume a deceased adult *Cardinalis cardinalis* (Northern Cardinal) in Muscatine Co., Iowa, USA, on 14 April 2001 (Swamp White Oak Preserve ca. 5 km NE of Conesville; 41.405973°N, 91.304328°W, WGS 84). The bird was decomposed to the point of desiccation, light in weight, and much larger than the snake (457 mm total length). The snake unsuccessfully attempted to dislodge the carcass from vegetation by pulling on it while the snake's posterior region was anchored in a small burrow for leverage. After ca. 5 min, the snake released its hold on the bird, fully emerged from the burrow and rested in the sun ca. 76 cm away from the carcass. On 19 July 1995, JCG observed a large female *T. sirtalis* (SVL = 840 mm SVL; tail length = 147 mm; 305 g without prey) with a large bolus at midbody in the northwest corner of Miller's Marsh not far from West Side Drive on Beaver Island, Charlevoix Co., in northern Lake Michigan, Michigan, USA (45.613397°N, 85.593722°W, WGS 84). The snake was captured and with gentle palpation a young (113 g) *Lepus americanus* (Snowshoe Hare) was regurgitated and preserved (deposited at Central Michigan University Museum of Cultural and Natural History). Examination of the hare revealed it to have a crushed skull, indicating that it had probably been killed by an automobile and then scavenged postmortem. Finally, at 2200 h (CST) on 14 June 1994, GSC observed an adult *T. sirtalis* in a tug-of-war with a *Carabus nemoralis* (European Ground Beetle) over a piece of carrion (a ca. 6 cm long frog limb, likely *Lithobates clamitans* or *L. pipiens*) on a rural gravel road in Forest Co., Wisconsin, USA (Berry Lane ca. 45 m E of Hemlock Creek; 45.479739°N, 88.876267°W, WGS 84). The beetle had one end of the carrion clamped in its mandibles while being dragged by the snake, its feet leaving furrows in the sandy road surface. The tug-of-war was observed for 1–2 min.; upon closer approach, the snake disengaged and fled, leaving the beetle with the carrion. The beetle was deposited at FMNH (determined by Robin Delapena). These observations lend support to the importance

of scavenging as a feeding strategy for *T. sirtalis* and report a novel prey item (*L. americanus*) for this species.

Cover Images for *Herpetological Review*

We are looking for photographic images to appear on future covers of *HR*. To be considered, preferred images should have the following qualities:

- Should be technically superior photographs (e.g., composition, lighting, etc., should be excellent; subject must be in focus).
- Should be taken in vertical format, or, if in landscape format, permit cropping to achieve a vertical orientation (2550 × 3300 ppi).
- Should be based on film or digital media; if the latter, the native resolution must be sufficiently high to permit cropping and/or enlargement to print publication quality.
- Preference will be given to images that depict poorly known species. These could include recently described taxa or species for which a color illustration has never been published.
- Preference will be given to images that communicate some aspect of the biology of the organism (e.g., predation, feeding, courtship, crypsis).
- Images should not have been published previously nor concurrently submitted for publication elsewhere (print or electronic media).

Images for consideration should be submitted as low-resolution jpg or pdf files. Do not send full resolution images unless requested to do so. All submissions or questions should be directed to the Editor (herpreview@gmail.com).

Although anoles might be better known as a remarkable example of adaptive radiation in the Caribbean, the dirty secret is this: the mainland has greater diversity. Our knowledge of mainland anole biology lags behind that of island species (Losos 2009), though various workers, Gunther Köhler and Randy McCranie included, have worked tirelessly to make up some of that ground. While basic ecological studies are still sorely needed for most species, large strides have been made in our alpha taxonomic knowledge in the mainland.

Which brings us to Honduras and this book. That *The Anoles of Honduras* can exist in its current form is a testament to McCranie, Köhler, Larry David Wilson, and colleagues. Thanks to these researchers, herpetologists now have access to several books detailing the herpetological diversity in this Central American country (McCranie and Wilson 2005; McCranie et al. 2006; Köhler 2008; Townsend and Wilson 2008; Köhler 2011; McCranie 2011). Much of what makes Honduras special is its location. Although the majority of Honduras lies within what is commonly known as Nuclear Central America, it differs from the other countries in the extent of biogeographic overlap with lower Central America. The book is therefore generally useful for the Nuclear Central American region as well as Nicaragua, and, to some extent, Costa Rica. Most major Central American anole species groups are represented in the Honduran anoline fauna, and this book is a solid place to become familiar with the morphology and basic natural history of Central American anoles. And, as far as anole expertise goes, the authors had a hand in describing 16 (out of 40, or 40%) of the species known from the country, which likely explains why the species accounts contain such detailed information. Clearly, McCranie and Köhler have spent countless hours in the field and looking at specimens, and this book would not have been possible without such dedication.

The book begins with an Introduction, a Materials and Methods section, and a brief overview of the history of anole work in Honduras. These sections are short and informative. After explaining their decision to use the Nicholson et al. (2012) taxonomic classification for anoles (discussed below), they briefly address the "ecomorph" vs "ecomode" topic that was also raised in the Nicholson et al. work (2012). I agree with the authors on this topic that the term "ecomode" was not well defined and that most of Nicholson et al.'s (2012) assignments were both subjective and based on very little information. McCranie and Köhler's decision to describe their direct ecological and morphological observations for the anoles of Honduras is much more useful than "ecomode" assignments would have been, and ecomorph assignments would have been equally inappropriate given the evidence that the well-defined island ecomorph classes are by and large unsuitable for describing the ecomorphological diversity of mainland anoles (Schaad and Poe 2010).

The authors made their case for the use of Nicholson et al.'s (2012) taxonomy for anoles as part of their Materials and Methods. I find their arguments to be misleading—the focus is mostly on Poe's (2013) statements on taxon sampling, data limitations, and monophyly among the proposed genera. Yet the most important arguments put forth by Poe (2013) for maintaining *Anolis* as a single, large genus lie in the fact that there are no scientific reasons to split up the genus that everyone acknowledges is monophyletic. There are numerous interpretations of the same phylogeny (i.e., generic divisions) that would be equally viable, and there is no objective reason to accept any particular arrangement over another. Alternative arrangements are presented in Poe (2013: fig. 1), along with a discussion for each. Nicholson et al. (2014) have made clear their purpose for dividing *Anolis* into eight genera: they want recognition of the genus *Norops* (Nicholson et al. 2012: p. 117), demonstrating the subjectivity highlighted by Poe (2013). Some will use the Nicholson (2012) classification for anoles but the majority of anole researchers have stuck to the one-genus arrangement for the time being. It should be noted that a rankless taxonomic system (PhyloCode: de Queiroz, 2006) would allow use of clade names without the problems that go along with the Nicholson et al. (2012) treatment.

The species accounts make up the majority of the book, and are more than worth the price of admission. This section is where the book shines and will prove valuable to researchers in Central America for the foreseeable future. There is a wealth of information on scale traits and coloration, useful for anyone in need of a data set for analyses involving morphology. There are figures, distributional information, and photographs for all 39 species from Honduras known to the authors (a 40th species, *Anolis wermuthi*, was reported from near the Nicaragua border shortly before proofs were finalized; Sunyer et al. 2013). Before this book, identifying anoles in Honduras required a fair amount

of knowledge and experience. Now a researcher or enthusiast can travel to Honduras and with a little investigative work, identify male anoles without too much trouble. The photos of the male dewlaps provided for each species are a key inclusion. Although some of the images are less than stellar, it's impressive enough that the authors were able to compile photos of all 39 species. This fact alone makes the book quite valuable.

I came across occasional mistakes in the species accounts but none were especially problematic. For example, in the *Anolis beckeri* account, the authors describe the distribution as occurring from the Mexican state of Tabasco to Nicaragua. The actual distribution of this species begins considerably farther to the north and west, into the states of Veracruz and Oaxaca, at the very least. The species account even references a population from Veracruz in the natural history section. Most mistakes were similarly small and of little importance.

The later sections of the book include a dichotomous key, assorted information on the distribution and biogeography, and conservation status. I found these sections to be generally informative, with some caveats. For one, anyone who has used (or attempted to use) Köhler's dichotomous key for anoles in *Reptiles of Central America* (Köhler 2008) is aware that this type of key is likely to test the patience of even the most level-headed herpetologist. There are too many species and many of the traits used are not easily scored, so that someone without much anole experience has no chance of effectively navigating through the key. The key in this book deals with fewer taxa and has more figures to help with scoring traits, but I must offer a word of warning for anyone attempting to use it alone as a way of identifying individuals: prepare for frustration. This is not the fault of the authors, of course—the species diversity and limited number of useful traits for identification are the true culprits. The best advice I can give for an inexperienced researcher/traveler is to find an adult male. Juveniles and even adult females are often remarkably similar between species. It's all about the dewlaps and the quicker you learn that, the better.

Unlike in much of Nuclear Central America, the mountain ranges in Honduras tend to be lower and less connected to each other, with the geographic separation perhaps producing a stronger pattern of isolation in the various reptiles and amphibians inhabiting the region. A number of endemic species have been described from Honduras in the past 20 years, and the rate at which they are being described has not slowed. This book offers considerable information on these endemics, allowing interested researchers an opportunity to pursue a multitude of questions relating to diversification in the region. For instance, why are there endemic species related to *Anolis laeviventris* in Honduras? *Anolis laeviventris* is currently considered to be a widespread species (from Panama to Mexico) and the presence of diagnosable microendemic species of this form only within Honduras seems odd. Phylogeography of the *A. laeviventris* group would be quite illuminating, as would further work on any of the anole groups generally considered to be composed of mid- to high-elevation isolates such as *Anolis pijolense* and *A. purpurgularis*.

One thing readers of this book may notice is the high number of subtly-diagnosed Honduran species that have small distributions and are presumed to be isolates of more widely distributed species (e.g., *Anolis bicaorum, A. morazani, A. roatanensis, A. rubribarbaris, A. utilensis, A. wampuensis, A. zeus*). I am hoping that this book will trigger further taxonomic work on these groups so that we can get a better handle on whether these purportedly isolated lineages are indeed legitimate species. For instance, the account for *A. wampuensis* states that the only major difference between this form and *A. tropidonotus* is an "extreme" difference in habitat—the latter has never been found in Honduras in "undisturbed broadleaf rainforest." The explanation seems strange, considering *A. tropidonotus* is found in a wide variety of lowland habitats (based on personal experience in both Mexico and Honduras) and there is likely to be very little undisturbed broadleaf rainforest left in the country. According to the book, *A. tropidonotus* is found in more departments than any other species in the country, has a wider elevational distribution than any other species, and occurs in the most "physiographic" areas as defined by the authors. And looking at the distribution maps, it appears *A. wampuensis* simply fills a small gap in the range of the more widespread, nearly continuously distributed *A. tropidonotus*. Minor dewlap differences have been reported, but that would be more consistent with some form of clinal variation in dewlap coloration, adaptation to local conditions, individual variation, or between-population variation. Complicating matters even further was the designation of *A. wampuensis* as one of the two most vulnerable anole species in the country, a bold assessment considering how likely this population is to simply be a representative of one of the least vulnerable anole species in Honduras (by any estimation), *A. tropidonotus*. While going through the species accounts, I was surprised by the number of species described with similarly limited evidence.

Some of these questionable species are diagnosed primarily based on limited observations of hemipenes, an increasingly common practice in anole systematics that I believe needs to be carefully evaluated and perhaps reconsidered. My concerns stem from a few observations made from published works, conference talks, and my own experiences working on the *Anolis sericeus* group. To begin with, it has been noted that hemipenes evolve much faster than other measured morphological traits in anoles (Klaczko et al. 2015). This fact alone can mean that differentiation in hemipenial traits can occur prior to speciation, and many species will be polymorphic for these traits. Furthermore, there is no evidence that reproductive isolation results from closely related populations with differentiated hemipenes. For example, Köhler and colleagues presented evidence against such reproductive isolation in follow-up work on *A. osa* (Köhler et al. 2012), which was described entirely on differences in hemipenial morphology (Köhler et al. 2010). Given the evidence from Köhler et al. (2012), the obvious conclusion is that *A. osa* should not be recognized as a distinct species. Results from a recent systematic study of the *A. humilis* group using molecular data (Phillips et al. 2015) were not consistent with Köhler et al.'s (2006) findings that relied heavily on hemipenial morphology. Finally, my own work on silky anoles (*A. sericeus* group) is in agreement with the *A. humilis* findings—evolutionary lineages, as deduced from multigene evidence (Gray, unpubl. data), are not at all concordant with the distributions of forms associated with hemipenes (Köhler and Vesely 2010). I worry that these traits have little to do with species differentiation and many species are being described under false assumptions. Even if hemipenial traits are found to be fixed within populations in anoles (a doubtful proposition given the rapidity of evolution in hemipenial morphology), intraspecific variation and interpopulation differentiation exist for many traits. The observation that a particular population can be diagnosed morphologically is not sufficient grounds for describing a population as a distinct species under any widely used species concept currently in practice.

To be clear, the issues I raised concerning species limits and taxonomy are largely the result of reading this volume, which contains a wealth of information. The authors present an account of the Honduran anole fauna that is more thorough than any previous summary of anole diversity for any country. *The Anoles of Honduras* is a must-have for any anole researcher in Central America and would be a good pickup for anyone with a general research interest on anoles. And I haven't even gotten to the best part—the price! Although one can order a hard copy for a very reasonable price, an electronic copy is free. The bar has now been set—it would be fantastic if someone could take on an even more challenging country such as Panama!

Bushmaster: Raymond Ditmars and the Hunt for the World's Largest Viper

Dan Eatherley. 2015. Arcade Publishing, New York (www.arcadepub.com). xxiv + 303 pp., 16 pp. pls. Hardcover. US $24.99. ISBN 978-1-62872-511-7.

RAYMOND J. NOVOTNY
Ford Nature Center, Mill Creek MetroParks, Youngstown, Ohio 44511, USA
e-mail: raynovotny@yahoo.com

JUST LIKE A COFFIN. So begins this part biography and part personal quest, sprinkled with just a bit of danger and death. Dan Eatherley immediately grabs the reader with his retelling of a scene from Raymond L. Ditmars' "Episode of the Bushmaster" from *Thrills of a Naturalist's Quest*, a 1932 classic I first read nearly 40 years later. In the prologue, "His Unwavering Grip," readers learn that the author is a British zoologist and filmmaker who discovered Ditmars while working on a project with Rom Whittaker in Costa Rica. He first wanted to make a film, but after 9/11 the industry changed drastically, eliminating that possibility. In his book, the bushmaster serves as a sort of "MacGuffin," the device filmmakers use to drive a story.

The author's approach, in fifteen chapters, each of which begins with a pithy Ditmars quote, is to alternate between his odyssey and a paraphrasing of stories Ditmars shared in his many books, or that appeared in *The New York Times* and other newspapers.

In "Working up Snakes" (the chapter titles are also Ditmars quotes found within the chapter. You'll have fun trying to find them!) a teenage Raymond L. Ditmars (RLD) meets "Professor George O'Reilly" at the Central Park Zoo. Is this perhaps his first introduction to the bushmaster? Eatherley accompanies Regina Alvarez of the Central Park Conservancy to Central Park and its Zoo, the first of many visits to Ditmars' haunts.

In "Pleased with a Rattler, Tickled with its Fang," in the library at the American Museum of Natural History (AMNH), Eatherley delves into how RLD's first association with science and scientists began. With several local herp enthusiasts, Peter Warny, Steve Ricker, and Erik Zeidler, he seeks snakes "within 50 miles of New York City" (also the title of RLD's first publication).

"Silent Death of the Black Night" begins with what is likely RLD's first long trip, by ship to Florida with John Bernhardt Smith, an entomological associate of his AMNH supervisor William Beutenmüller. RLD's family allows snakes in their new home, and he strives to fill up the attic. R. R Mole of Trinidad, who would supply the original bushmaster, appears.

In "The Master of Snakes," after much difficulty, Eatherley succeeds in finding Edwin McGown of the Palisades Interstate Park Commission to escort him to Timber Rattlesnake (*Crotalus horridus*) dens RLD might have visited. The famous "Episode" is touched upon. RLD's fame begins as does his reporter position with *The New York Times*.

"A Snapping Turtle in a Tin Bathtub" opens with the American Inter-Continental Exhibition of Reptiles, a large event RLD assisted in organizing, that might have been another reason William Hornaday offered him a position at the New York Zoological Park. The origin of what came to be called the Bronx Zoo encompasses the bulk of this chapter. Eatherley peruses the scant Ditmars material in the zoo library, disappointed about not finding a single reference to bushmasters.

"A Decided Awakening of Unbiased Interest" revisits opening day of the Bronx Zoo, 8 November 1899, and delves into the early years. Eatherley visits the Reptile House, now rebranded "World of Reptiles" with collections manager Chris Hutson.

In "Reptilian Deviltry of the World," RLD and head keeper Charley Snyder recapture two immense King Cobras accidentally released by animal dealer William Bartels. They later force feed a python. At the "best Italian restaurant in the Bronx" Eatherley visits Bronx Zoo retiree Peter Brazaitis, who regales him with stories, probably also published in his memoir, *You Belong in a Zoo!* The next day Peter takes him to the New York/Connecticut border where RLD likely searched for *Crotalus horridus*. Eatherley discusses RLD's attempts at veterinary work.

"A Sort of Freemasonry" opens with RLD and his family, keeper Snyder, and several others in South Carolina. The Pinelands Club there served as the base for collecting southeastern species for the zoo collection. His two teen daughters stayed back at a cabin during the hunt and with their grandfather, end up catching the biggest diamondback! With Ed McGowan, Eatherley returns to timber country and almost steps on one. We learn about the bite that Ed's colleague, William H. "Marty" Martin, survives.

RLD, with Snyder's assistance, milks a Fer-de-lance (*Bothrops asper*), which introduces "A Messy Business," a chapter about snakebite and its treatment both now and years ago. In the zoo archives again, Eatherley now reads over bushmaster records in bulletins and reports. None survives long. Curator Don Boyer explains the success of keeping them now.

In "A Sympathetic Knowledge," after depicting a performance of the Bronx Zoo Reptile Circus at the Waldorf-Astoria, Eatherley sits in the New York Public Library and pores over articles featuring Ditmars, leading to a discussion of RLD's own writing, declaring it "precise, readable, and entertaining." He mentions something I've always cherished: President Theodore Roosevelt's praise for *The Reptile Book,* including an open invitation to the White House. Can you imagine that happening today? There's an overview of RLD's attempts at research in primate intelligence and his public speaking. His lectures, of course, always included live animals and photographic slides. Soon he would incorporate another medium.

"The Stage of Nature" begins with RLD, his wife Clara, and assistant "Andy," filming a Fer-de-lance at the Ditmars' residence. The scene, of course, goes awry with the serpent unexpectedly slithering off stage down to the floor. "Don't worry," laughs Clara struggling to her feet. "It missed!" Eatherley visits the Westchester County Archives where he studies a copy of the Ditmars' will: Approximately 270 cans of film, perhaps 300,000 feet and 150 hours of viewing, appraised at $5000. Although few now survive, these enhanced his lectures and were even shown in movie theaters. "Andy" convinced RLD to add the emotion and humor the theaters demanded, resulting in "The Jungle Circus" eventually the ending of his six-reel masterpiece "The Book of Nature." Our author/filmmaker provides pages of details of RLD's work with film. He savors the existing films he views at the Library of Congress.

Finally to the tropics in "A Naturalist's Paradise"! The Ditmars family spends *muchas semanas en Honduras* battling mosquitos while searching for snakes. The author visits the Smithsonian's Museum Support Center and examines preserved specimens associated with RLD. He sees his first bushmaster, albeit pickled. After retelling the story of the Zoo's first-ever snakebite in 1916, which almost killed keeper John Toomey, he introduces the Antivenin Institute of America.

In "The Main Thing Is the Bushmaster," RLD searches successfully for vampire bats in Panama, accompanied by Arthur Greenhall, perhaps somewhat the son he never had, but yet again strikes out with *Lachesis*. Eatherley fares better during his visit with Dean Ripa at his Cape Fear Serpentarium in North Carolina, where he finally sees living bushmasters.

"Six Feet Long and Vicious" focuses on Trinidad. R. R. Mole had sent the bushmaster featured in the "Episode," and almost every other specimen exhibited at the Zoo, from there. Both RLD and Eatherley visit the island nation. Thanks to his colleague Friedrick Willlliam "Jangoon" Urich, RLD brings back the Zoo's first specimen in decades. Eatherley begins networking for advice about bushmasters. At the Emperor Valley Zoo, he talks with keeper Delbert Charleau, Jr. With his cousin's husband Ian, a native Trinidadian, they seek out Delbert's former supervisor, Hans Boos, author of *Snakes of Trinidad and Tobago,* and "Snake Man" Allan Rodriguez. No one offers a technique guaranteed to find a bushmaster.

Still on the island in "We Can Get All We Want Now," Eatherley rendezvous with long-time SSAR member John C. Murphy, a Chicago-based specialist of Trinidad and Tobago herps, his friends Gabriel Hast and Tom Anton, guides Mukesh Ramdass and Molly Calderon, and Abraham Diaz, a photographer for the *Trinidad Guardian*. They examine a recently killed bushmaster at the Asa Wright Nature Center and search for a live one. Were they successful?

In "Epilogue: My Happiest Hours" Eatherley overviews both the dubious future of the world's largest viper throughout its range and the remarkable career of its seeker.

To conclude, in "Author's Note: Meeting Gloria" Eatherley introduces us to RLD's only grandchild, describing her as inheriting her grandfather's physical features. She reminisces about her "Pop," ("…just *delicious*…A character, a dignified character.") playing at the zoo, and travelling to the West Indies.

I'm honored to be among the many listed people in the three pages of "Acknowledgements."

Toward the middle are eleven pages of contemporary color photographs of snakes and people, the final one is Gloria holding a large portrait of her beloved grandfather. Five more pages of black & white from RLD's era follow. I counted 17 similar images scattered throughout the text.

At the American Museum of Natural History, Eatherley discovers two letters written by RLD's father to curator William Beutenmüller about a position for his son. He rightly declares these documents as a defining moment in RLD's career. While I appreciate the word-for-word transcriptions (pp. 22 and 24), photographs of John V. H. Ditmars' "elegant flowing hand" would have been even better.

I learned several new words, including "gormless" (page 23) for "stupid" and the possible origin of the name bushmaster, from *bosmeester* coined by Dutch explorers (p. 50).

I found few misspellings or factual errors, although I've never heard of "green chicken snakes" (p. 9). The statement about the lack of hearing in snakes (p. 178) might have been updated.

Common names are not consistent: On p. xix, rat snakes, yet coralsnakes; on p. 27, watersnakes, yet garter snakes. Perhaps consulting Crother (2012) would have been wise.

Eatherley corrects the error of the only prior Ditmars biographer (Wood 1944), C. *Stover* Allen to C. *Slover* Allen, a physician interested in snakebites. While on the subject of errors, I would like to discuss the dilemma of the birthdate of Raymond L. Ditmars; I hope not too trivial a point.

His obituaries stated his birthdate as 20 June 1876, as did Albert H. Wright (1949). The death record instead lists 22 June (I have my suspicions about the disparity). His biographer, Laura Newbold Wood Roper (1994), Kraig Adler (1989), and Eatherly all repeated the 22nd. As recently noted by Adler (2014), I obtained a document from the New Jersey Archives that substantiates the correct birthdate as June 20. So we'll wish a happy 140th birthday to RLD on the Summer Solstice 2016!

When I was fervently "following the Ditmars trail" (p. 275) especially at the turn of the century/millennium, it took a couple of years and couple of hundred dollars to locate his only grandchild, Gloria. "Pop" dedicated *Confessions of a Scientist* to her when she was about six and half years old, and she may be the only person still alive who knew him. I put Eatherley in touch with Gloria and I'm so happy he devoted four pages to her. To my inquiry whether her grandfather had a New York accent, she had said no, so Eatherley's observation after viewing/hearing a "talkie" titled *Killing the Killer,* "the New York inflection obvious" (p. 200) was quite a revelation.

Eatherley and I were in touch off and on during his project, but now I lament we did not collaborate more. Although he quotes me correctly about the family throwing everything away, at a later point I learned some specifics of a book sale in the late 1960s. What a tragedy for posterity that so few of RLD's "papers" survive.

Eatherley suggested visiting me, but I discouraged him from devoting the precious time and money because I wondered how much insight I had to offer. Upon reflection, and after reading about the others he met, I too could have shown him some snakes, taken him out to eat, to bond as kindred souls, and filled him in about how I've tried to lead a Ditmarseque life in a so much more modest way in my Rust Belt city [look how my byline copies the "cadence" of Raymond L.(ee) Ditmars], and shared my cherished complete book collection. That might have merited one of his color photos?

A list of illustrations is often standard companion to a table of contents, but is lacking here. I liked how Eatherley often included RLD's age at the time of a given narrative and would have much appreciated a timeline about his life. If provided, I would have referred to maps of significant places such as "within 50 Miles of New York" and Honduras, Panama, and Trinidad, etc. But of course, I have atlases and Internet access.

Eatherley uses a storyteller style and paraphrases Ditmars' writing, and that of others, throughout. And that of others. For example, I immediately recognized familiar passages such as Adler (1989, 2014) on p. 173 and Kate Swan's 1897 newspaper article (pp. 63–64) that I annotated a century later (Novotny 1999). I wish that all the others were cited with notes and a bibliography. I began to search, with some success, for those in my Ditmars collection and *The New York Times* online archives, but this painstaking process would have held up this piece until the next issue of *Herp Review*.

In 1989, Kraig Adler wrote, correctly, that Ditmars had influenced many herpetologists still active. A decade later I expressed concern that Ditmars was being forgotten. Dr. Adler assured me that, because of the continuing availability of his books, that was not the case at all.

I'm not sure if he fully convinced me, but with Dan Eatherly's labor of love now published, Raymond L. Ditmars is back in the news, and I hope it leads to a resurgence of appreciation. I enjoyed this book immensely and recommend it to everyone interested in him, herpetology, or a good story. Buy one for yourself and for those on your gift list. Every library in the English-speaking world should own it. And despite the judgment that RLD's writing is "peppered with behind-the-scenes anecdotes too topical to stand the test of time" (Goddard and Swope 1995), admirers of *Bushmaster* may want to delve into RLD's original works, too.

Recall that this project originated with Dan Eatherly's idea for a film featuring Raymond L. Ditmars. I'm sure he could make a movie just as good as his book. But who should be cast as the bushmaster hunter? Chris Pratt starred in last summer's blockbuster *Jurassic World* and is the rumored successor to Harrison Ford in the next installment of the *Indiana Jones* franchise. In the meantime, would he be willing to grow a mustache and don some leather puttees?

If you are like me, you have a well-used copy of Petranka's (1998) *Salamanders of the United States and Canada* sitting bruised and loyal within arm's reach of your work desk. That book has been with me on field trips to the Appalachians, the Northwest rainforests, and the swamps of south Georgia, but unfortunately it doesn't get used much anymore since I now live in the desert. But it is nice to know those thorough species accounts are there, and as a natural history editor for *Herpetological Review* I do get to flip it open every now and then to check up on somebody's facts. So, when I heard about the new book *Salamanders of the Old World* by Max Sparreboom (2014), I thought I should get it right away, even though I have never been to Europe or Asia. Maybe just having such a book would in some way transport me to misty Mediterranean cliff faces populated by *Speleomantes*, or tumbling splash zones of Colchian streams teaming with *Mertensiella*. And it would possibly be a necessary reference for those occasional natural history observations sent from Eurasia. I bring up Petranka because the inevitable comparison between Sparreboom's book—especially for North American readers—will be to *Salamanders of the United States and Canada* (although, covering 160 versus 127 species, Sparreboom had a bigger task and certainly a much bigger geographic scope).

This hardcover book is wonderfully designed, with 431 glossy pages each laid out slickly, and richly illustrated with full-color photographs of adult and larval salamanders as well as egg sacs (only three species are not illustrated with photographs—one of which has not been seen since it was described in 1910), photographs of habitats and landscapes, illustrations from classic texts, line drawings, range maps, and a frontispiece showing salamander morphology. The book begins with an excellent introduction covering basic salamander biology, reproduction, evolution, and conservation. The book is then organized alphabetically by family, genus, and species names. Each family section has a detailed familial summary, and each genus is similarly (if a bit too technically) summarized. There are individual accounts for all the species covered with sections on their general description, diagnosis, eggs and larvae, distribution, habitat, behavior, threats and conservation, observations in captivity, and taxonomic comments. A reference section follows each account. Many of the species accounts are spare and repetitious, since only one or two of the species within any of the genera are well known. There is a glossary and thorough reference list.

I thought it was a good attempt by Sparreboom to include the "observations in captivity" section to simultaneously appeal to the herpetoculture crowd and also demonstrate that much of our knowledge of the interesting courtship rituals of many salamanders comes from captive observations. The taxonomy is up-to-date and follows recent work by Pyron and Wiens (2011); a phylogram is provided showing familial relationships and the generic relationships within the largest Eurasian family Salamandridae. The book is ambitious in scope both in terms of geography, topics, and the number of species involved. Sparreboom admits the book is an attempt to update Robert Thorn's treatise on Old World Salamanders (1969), and pays appropriate homage to this author and work. So how does Sparreboom's book measure up?

I have to point out that I am no expert on Old World salamanders so I can't be trusted to determine the overall accuracy of the book. And while I cannot say how well the book replaces Thorn (that book is in French), I should mention that my comparison to Petranka (1998) is not entirely fair. Sparreboom does not set out to write a book as comprehensive and detailed as Petranka's. For me this was frustrating, but then again I am an inveterate salamander nerd. Although not written at a juvenile level, the book for the most part could be understood by a student, which is probably for the best. It could easily be argued that Sparreboom's approach—a richly and beautifully illustrated book spare on details but filled with references guiding true nerds to the published literature—is actually superior to the more thorough approach of Petranka. But I personally would have rather had a more complete summary of the literature. And in some cases Sparreboom mentions interesting details and does not expand upon them, instead referring us to citations. This was his worst offense, and the best example of this is found on p. 161 when Sparreboom mentions tantalizingly that *Speleomantes sarrabusensis*, a plethodontid, might be viviparous. He mentions this bombshell only in passing and refers the reader to a reference that is not in English, leaving the poor English reader (for the record, the book is in English) to wonder about this incredible fact and why it is suspected to be true. Something like this needs to be covered in a book like this, not simply mentioned and cited.

In other cases, Sparreboom appears to simply be reiterating every detail from another account (e.g., the descriptions for many *Hynobius* rely heavily on Thorn), or worse yet, from an online source (e.g., amphibiaweb.org; salamandersofchina.org). Sparreboom mentions that this book grew out of an attempt to archive natural history information on Old World salamanders on a website, thus the web citations and thin species accounts; for the book, primary literature should have been used.

In terms of illustrations, Sparreboom's book is certainly far superior to Petranka's. All but a handful of the salamanders covered are illustrated with large, full cover photographs of living individuals, most of them taken *in situ*. These include gorgeous photographs of gorgeous salamanders taken from some rather unreachable locations, such as Syria, northern Iraq, and Iran. Many of the photographs were taken by Sparreboom himself, who must have racked up some serious frequent flyer miles and must have some great stories to tell about his travels.

This brings me to another disappointing aspect of the book. Sparreboom presumably has extensive first-hand experience with many of the salamanders he covers (in the field and in captivity), but this is not conveyed in the writing. It is certainly evident from his photographs, which include pictures of living salamanders and also their habitats (a very nice touch). Sparreboom has presumably seen more of these species firsthand than anybody else alive, or at least anybody else alive who has tried to write a book about them. But this firsthand knowledge does not bleed into the

species accounts. Many are instead spare and based on sketchy sources, and are inordinately preoccupied with mating behavior. It made me wonder if a much better book could have been written by Sparreboom had he kept detailed field notes of his encounters during his travels. Or, if a better book could have been written by a team of European, Chinese, and Japanese authors, since many of the Asian species have an extensive, un-translated literature that Sparreboom tells us about but does not attempt to summarize. A bias toward the European species is definitely evident, although this was both inevitable and forgivable. The species accounts for European species are much more thorough and well researched, and this is where Sparreboom's book becomes more comparable to Petranka's.

Another area where the book is definitely weak is the range maps. The maps are topographic but not at a scale where this was warranted. At the scale of the entirety of China, showing topography just muddles the picture. The distributions of most species are plotted with hashed lines that are too similar in color to the topographic lines, so most of the maps are difficult to interpret. Although there are maps in the back of the book that allow the unfamiliar reader to refer to various regions of southeast Asia and Europe, I doubt if even a resident of Turkey would be able to locate themselves relative to the range maps of *Lyciasalamandra* found on p. 241. An inset showing the relationship of the distribution to a larger, more recognizable region (all of Asia, or Europe) was needed for nearly all the maps, and a fully grey-shaded distribution blob (as in Petranka) would have been much better.

I don't get much satisfaction from reading lists of slight errors in book reviews, but I will mention that there were some (as one might expect from a book with 431 pages), but not many. After going through the whole thing I only found around twenty. These ranged from obvious formatting errors (such as p. 144 where the illustration overlaps the figure legend text) to redundancies (p. 311, column 2, line 11, the color description of *Salamandra salamandra* is stated twice within the same section), and simple mistakes (pp. 126 and 130, Sparreboom mentions that *Paradactylodon* are active at night outside caves "where the difference between day and night is not apparent").

On the other hand, for every slight error like this, I probably learned one or more remarkable facts that I was not aware of before reading this book. The line drawings of hynobiid egg sacs are weird and terrific. The description of hynobiid males pulling eggs out of the female while simultaneously kicking her away, so that he may fertilize them in privacy, is hilarious and a strange curiosity of natural selection. The book has nuggets of intrigue and mystery: the lost *Hynobius* of Turkestan, and the presumably extinct *Cynops wolterstorffi*—a salamandrid endemic to a single lake in China that was once common but has not been seen in decades. Strange reproductive features I was unaware of are described and illustrated: the hypertrophied thighs of *Onchodactylus* used in amplexus, and the spectacular dorsal tail knobs of *Lyciasalamandra* and *Mertensiella*, which are used during courtship to stimulate the female cloaca while males hold them on their backs in ventral amplexus. *Echinotriton* males secrete a wispy spiderweb of mucous from their cloaca as they court females, possibly tying them down for positioning the spermatophore. For me, these wonderful natural history stories and their accompanying illustrations make the book worth the exorbitant US $134 price. As I told one interested but reluctant colleague: relax, you are simply paying less than a dollar for each species account.

That price will probably cost this book most of its potential readership. But libraries across Eurasia and North America should have this book, as well as some die-hard collectors like me. The information on captive husbandry undoubtedly will be useful to the thriving salamander herpetoculturalist crowd in Europe. But I'm not sure if this book will become a dog-eared and battered field companion for anyone in Eurasia, much less for curious readers in North America looking to plan their next vacation. So maybe there is room for improvement and there might still be a book waiting to be written that could aim to be a well-illustrated "Petranka for the Old World." But for now Max Sparreboom's nice book will do just fine if you can afford it.

"*America is proud of her magnificent record in road building, but nothing has been so destructive of wild life as our good roads.*"
—Thomas Barbour, 1944

This book is for people seeking ways to lessen the impact of roads and vehicular traffic on amphibians, reptiles, and mid- to small-sized mammals (i.e., "small animals" in the editors' parlance) and their habitats and populations. The text on the back cover states that this is the first book to focus on "improving outcomes where transportation needs and small animal habitats overlap." Well, not exactly. Langton (1989) published the first book of which I am aware on resolving and mitigating conflicts between amphibians and roads, and made it available to participants of the First World Congress of Herpetology in England that year.

The editors seem to imply in the Introduction that the term "ecological infrastructure" is novel; they provide no evidence to the contrary. The term was first used in a 1984 report by the Man and Biosphere Program to the United Nations Educational,

Scientific and Cultural Organization (UNESCO) (Wang et al. 2008). It was used initially to represent the habitat network and emphasized the biodiversity conservation functions of many landscape components, such as corridors. There are several other definitions usually associated with urban ecology (Banzhaf and Netzband 2011). The editors of this book define ecological infrastructure as "*the basic habitat components and their connections necessary for species survival, and for natural populations, communities, and ecosystems to function properly.*" A primary goal of the editors is to broaden the reader's view of road impacts on small animals by providing the ecological context within which the public infrastructure (roads, bridges, etc.) functions. Information presented in the book demonstrates the many ways they are intertwined. The book is a call to action for researchers, engineers, landscape planners, and others involved with road ecology to collaborate better than they usually do to reach common goals.

Road construction and the resulting mortality of small vertebrates has been abundantly described from early in the 20th century onward. Efforts to do something about it began with the use of signs in the early 1960s in Europe. Underground passages appeared in the late 1960s. Underpasses in the United States were first constructed in the late 1960s along I-75 which cuts across the Everglades between Ft. Lauderdale and Naples. Nearly all of the examples of road and wildlife conflicts in the book are from Europe and the United States. Projects in other regions such as South Africa are rarely mentioned.

Following a review of the history of road ecology, three chapters address the natural history of small vertebrates, direct effects like roadkill, and how habitat modification, in turn, affects their survival and persistence. Information and examples focus mostly on amphibians and reptiles. There are substantially fewer examples and discussions on mammals. Chapter 2 includes a long list of topics on animal behavior, movements, physiology, and other aspects of species biology. Chapter 3 on direct effects includes the important topics of road mortality, roads as barriers, road density, habitat fragmentation, and landscape genetics. How roads affect habitat quality, covered in Chapter 4, focuses on effects of chemicals such as heavy metals, road salt, and other forms of pollution, environmental stressors such as moving and stationary lights, habitat modification, human access, and animal behavior.

Chapters 5–12 cover numerous practical topics ranging from public education to road construction specifications. The authors in these chapters include a breadth of subjects within their topics: planning and design, funding, mitigating road effects with structural modifications, modifying structures on existing roads, construction and maintenance, and monitoring and adaptive management. Numerous case studies and photographs illustrate specific points. This is not a technical manual, although design specifications for culverts, underground passageways, and barriers appear in Chapter 9. The authors provide realistic descriptions of processes and challenges, background where needed, and evaluations of problems and solutions pertinent to their topic. One comes away realizing there are many complexities involved with solving any road and wildlife problem. In the last chapter, Andrews lays out a general, multifaceted overview of where future efforts should be made, but offers few specific targets.

Each of these chapters ends with a section of bulleted Key Points that reviews the highlights and messages the authors consider important. Fortunately, literature citations are provided at the end of each chapter making it easier to connect a point of discussion with its corresponding literature. There are two lengthy practical examples on road problems and solutions by guest authors. One focuses on turtle mortality on a causeway to a barrier island and the other on the effectiveness of New York State's first amphibian tunnel. Embedded within each chapter are one or more short case studies by other authors. The index covers topics but not species.

This is a handsome, well-constructed book, although I was annoyed with the low quality of the black-and-white photographs. The layout includes three layers of section subtitles that break up the text into manageable units to enhance readability. I would not buy the eBook version because it costs as much as the hardcover version.

Everything humans do with and on roads causes a long list of problems for small vertebrates. This book provides information on and solutions for many of them. Some of the same topics are explored in Forman et al. (2003), as well as others not discussed in Roads and Ecological Infrastructure. The latter does not establish the background on road densities and mortality statistics needed by newcomers to understand why this is such an important subject critically in need of resolution. People interested in road-vs-wildlife issues should read both of these books to get a thorough overview of the seemingly intractable problems roads create for small animals.

HERPETOLOGICAL NOMENCLATURE

The years 2013–2014 have been especially controversial ones insofar as herpetological nomenclature is concerned. It began with an article in this journal by Kaiser et al. (2013) recommending a standard of best practices for systematic herpetology. The article in particular reviewed the practices of R. T. Hoser and his notorious *Journal of Australasian Herpetology*. In that "journal" he has created hundreds of taxonomic names proposed in ways that most herpetologists think do not meet the conditions for publication required by the International Code of Zoological Nomenclature (International Commission of Zoological Nomenclature 1999). In what is clearly a ploy to legitimatize his journal, Hoser has applied to the Commission in Case 3601 (see below) to endorse his claims that his "journal" meets the requirements of the Code thereby making his multitude of new names available.

Kaiser et al. (2014) countered Hoser's contentions and there is widespread support in the herpetological community for placement of all issues of the *Journal of Australasian Herpetology* on the Index of Rejected and Invalid Works in Zoological Nomenclature. This action is certainly within the purview of the Commission under Arts. 78 and 81 relating to the Plenary Power, which may be invoked to suppress a particular name or works that would "disturb stability or universality or cause confusion."

The problems raised by the Hoser case clearly test the long held notion that the Commission not make judgments on the taxonomic quality of an author's work by applying the Code in as neutral manner as possible. Nevertheless, in ruling on individual cases presented to the Commission, the attempt at neutrality is not uniformly successful. In almost all cases, there are differences of opinion among the Commissioners, hence the requirement that approval of most applications be a simple majority, but where the Plenary Power is involved a two-thirds majority is required for approval. Because of these concerns, Commissioners Harvey and Yanega (2013) prepared a brief, very thoughtful, document requesting advice from the taxonomic community as a whole on possibly changing the guidelines for Commission actions to deal with such extreme cases as Hoser's. They asked that responses address the issues they raise not the specific case that has led to the controversy. The results of their survey have not yet been published and there is still time to comment anonymously on their questions via the Commission website.

While all this activity was going on, major changes took place in the location and operations of the Commission. A major financial crisis led to the dissolution of the International Trust for Zoological Nomenclature that had long been the financial entity supporting Commission activity. In another move, the University of Singapore agreed to provide space and staff for the coordinating activities of the Commission, for three years. A small staff, including the editor of the Bulletin of Zoological Nomenclature (BZN), will remain at the Natural History Museum in London. Visit the ICZN website (http://iczn.org/) for more details. The University of Singapore's rescue is temporary and it remains to be seen if the Zoological community will rise to the occasion and develop a funding plan that insures the continuance of the vital functions of the Commission.

Recent Rulings on Herpetological Names
(BZN = *Bulletin of Zoological Nomenclature*)

Opinion 2328 (Case 3571). *Crotalinus catenatus* Rafinesque, 1818 (currently *Sistrurus catenatus*) and *Crotalinus tergeminus* Say in James, 1822 (currently *Sistrurus tergeminus*; Reptilia, Serpentes): usage conserved by designation of neotypes for both species. BZN 70(4):282–283.

Opinion 2331 (Case 2331) *Cetiosaurus* Owen, 1841 (Dinosauria, Sauropoda): usage conserved by designation of *Cetiosaurus oxoniensis* Philipps, 1871 as the type species. BZN 71 (1):48–50.

Opinion 2350 (Case 3566) *Tropidolaemus* Wagler, 1830 and *Cophias wagleri* F. Boie, 1827 (currently *Tropidolaemus wagleri*) (Reptilia, Squamata, VIPERIDAE): usage conserved. BZN 71 (4):271–273.

Pending Cases of Herpetological Interest

Case 3625. *Kinosternon chimalhuaca* Berry, Seidel, & Iverson in Rogner, 1996 (Reptilia, Testudines): proposed confirmation of the publication date. BZN 70(3):190–102.

Case 3628. *Terrapene putnami* Hay, 1906 (Testudines, EMYDIDAE): replacement of the holotype by designation of a neotype. BZN 70(3):193–198.

Case 3601. *Spracklandus* Hoser, 2009 (Reptilia, Serpentes, Elapidae): Request for the confirmation of the availability of the generic name and for the nomenclatural validation of the journal in which it was published. BZN 70(4): 234–237.

Case 2641. *Ascalabotes sthenodactylus* Lichtenstein, 1823 (currently *Stenodactylus sthenodactylus*; Reptilia, Gekkota, GEKKONIDAE): proposed conservation of current usage of the specific name by designation of a neotype. BZN 71(1):17–21.

Case 2629. *Vipera latastei* Boscá, 1878 (Reptilia, Serpentes, VIPERIDAE): request for conservation of the original spelling. BZN 71 (1):22–25.

Case 3666. Dicroglossidae Dubois, 1987 (Amphibia, Anura): proposed conservation. BZN 71 (4):244–249.

What are the Correct Family Names for the Taxa that include the Snake Genera *Xenodermus*, *Pareas*, and *Calamaria*?

We all know that the scientific names of organisms are mostly derived from Classical Greek and Latin. Once the Linnean binominal system of nomenclature became firmly established by the early 19th century, individual species names consisted of a genus name and a specific epithet (e.g., *Heloderma horridum*). Genus-group names traditionally, and according to Art. 11.8 of the International Code of Zoological Nomenclature (International Commission on Zoological Nomenclature, 1999), must be singular and in the nominative case (the equivalent of the subject of a sentence in English). All zoological names must be in the Latin alphabet and genus-group names may be a Greek noun transliterated into Latin, a Latin noun, or a latinized version of a Greek noun with a change of ending and treated like a Latin noun. Unlike English, Greek and Latin nouns have gender, they are feminine, masculine, or neuter (*f. m. n.*). Gender may be determined by reference to Greek or Latin dictionaries. Many generic names are compound words, for example *Heloderma* (*helo* = wart; *derma* = skin). The gender of the genus name is determined by the terminal noun's portion. In the case of *Heloderma*, as *derma* is a Greek neuter noun transliterated into Latin, *Heloderma* is neuter too. In this example, the specific epithet for the Mexican Beaded Lizard, is *horridum*, an adjective that must agree in gender with the generic name. Genus names derived from other languages or formed as arbitrary combinations of letters have their gender determined by special rules.

Family names must be derived from the nominative plural form of a genus name by adding the suffix –idae to the noun's stem. In the example of *Heloderma,* the plural is Helodermata, the stem Helodermat–, and the family name derived from it is Helodermatidae. Other suffixes are used for other family-group names: superfamilies –oidea, subfamilies –inae, tribes –ini, and subtribes –ina.

We now examine the situation of the family name based on the snake name *Xenodermus* (*xeno* = strange; *dermus* = skin). Reinhardt (1837) named this genus for the new species *Xenodermus javanicus*. The family-group name Xenoderminae was proposed by Cope (1900:731). For most of the 20th century, the names Xenoderminae, Xenodermidae, or Xenodermini were used universally as family-group names for *Xenodermus* and several subsequently described genera (e.g., *Achalinus*, *Fimbrios*, *Stoliczkaia*, and *Xylophis*) whenever the clade was accorded family-group status (e.g., Smith 1943; Bogert 1964; David and Vogel 1996). More recently, some authors (e.g., Zaher 1999; Vidal et al. 2007; Grazziotin et al. 2012; Pyron et al. 2013) cite the family-group name as Xenodermatidae or Xenodermatinae.

The authors of these papers apparently think that *Xenodermus* is a neuter Greek compound noun like *Heloderma*. This is not the case. The latinized version of the Greek noun *derma* (*f.*) is *dermus* and compound nouns based on the latter must take the gender (*m.*) indicated by its Latin suffix (–us). It was clearly Reinhardt's (1837) intent to coin a Latin generic name of the masculine gender as indicated by his coupling of *Xenodermus* with the specific epithet *javanicus*, a masculine adjective agreeing in gender with the generic name, not the neuter *javanicum*. Consequently, the correct family name is Xenodermidae Cope, 1900, not Xenodermatidae.

A slightly different situation involves the family name for the snake genus *Pareas* Wagler, 1830. *Pareas* is a latinized Greek masculine noun *parieas* with the "*i*" ellipsed that means a kind of snake. Authors in the 20th century (e.g., Smith 1943:117–121; Romer 1956:583; David and Vogel 1996:138) have treated *Pareas* as masculine.

The first use of a family-group name for this genus is by Romer (1956:583), who proposed the subfamily name Pareinae. Dowling and Duellman (1978:112b.3) introduced the tribal spelling Paretini [sic] without comment. Recently, some authors (e.g., Zaher 1999; Vidal et al. 2007; Grazziotin et al. 2012; Pyron et al. 2013) use the family-group name Pareatidae or Pareatinae for this group of snakes. The latter authors, perhaps influenced by Dowling and Duellman (1978), seem to have thought that *Pareas* is of neuter gender and its combining form is *pare*–, the nominative plural *pareta*, and the stem *paret*–. If that were the case, as in the example of Helodermatidae, the family name would be Paretidae. That interpretation is not tenable as *Pareas* is masculine, its nominative plural is *pareae*, and the stem is *pare*–. Consequently, the correct formation of the family name derived from *Pareas* is Pareidae Romer, 1956.

The genus name *Calamaria* was proposed by H. Boie in F. Boie (1827:519). It is a Latin masculine adjective used as a noun (*calamaria* = having the nature of a reed; a writing reed; a reed for holding a pen). The type species of *Calamaria* is *Calamaria linnaei* H. Boie in F. Boie, 1827 by action of the International Commission on Zoological Nomenclature in Opinion 2196 (2008). The family-group name Calamarina was proposed by Bonaparte (1838:125). Under the current rules of nomenclature the proper spelling is Calamariina. Bonaparte appears to have ellipsed the –ii into a single –i. Consequently, the correct spelling for the family name is Calamariidae.

SSAR and PARC: A Synergy of Science and Conservation Action

The July 2015 meeting of the Society for the Study of Amphibians and Reptiles (SSAR) in Lawrence, Kansas, served as a unique opportunity to formalize and enhance the relationship between Partners in Amphibian and Reptile Conservation (PARC) and SSAR. Throughout PARC's now 16-year history, SSAR members have engaged in PARC meetings and vice versa. However, this was the first time we collaborated directly on conference content. As part of this strengthened relationship, PARC was asked to put together an article for *Herpetological Review* about our past accomplishments and current activities. In particular, we were asked to consider where SSAR members fit into PARC's past, present, and future. The answer: Everywhere!

PARC's mission: *To conserve amphibians, reptiles and their habitats as integral parts of our ecosystem and culture through proactive and coordinated public/private partnerships.*

As we all know, effective management and conservation is dependent on sound science. Researchers are compiling an immense amount of data via an ever-increasing toolbox of techniques, which has the potential to fundamentally change conservation actions. However, all too often individuals charged with making policy or on-the-ground conservation decisions are unable stay abreast of the most current findings to improve and enhance management and policy decisions. To further compound this problem, researchers often struggle to get their findings into an application setting for natural resource managers. Enter PARC, whose mission is accomplished through partnerships—we engage experts in both the science and management realms to achieve conservation guidance and on-the-ground action. We provide recommendations and guidelines based on sound science and common sense; we also facilitate real conservation action.

PARC's Vision: *To provide leadership in the implementation of effective amphibian and reptile conservation on a local, state, regional, national and international scale in order to foster improved conditions for amphibians, reptiles and their habitats; one where common species remain common, and the future persistence of endangered and rare species is more certain.*

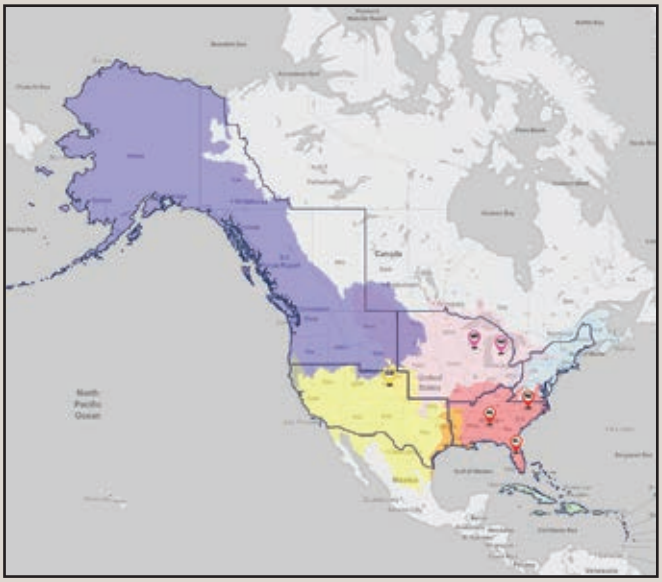

FIG. 1. Map of PARC regions, with regional working groups outlined in black, based on political boundaries. However, colored shading based on ecoregional boundaries is also included to depict how people may engage in PARC based on the location of their species of interest, research sites, or habitats with which they are most familiar; there are no constraints for participation solely based on physical address.

The partnership that comprises PARC is diverse, and includes representatives of government, industry, nongovernmental organizations, private consultants, interested individuals, and academia. Our membership now extends from western Canada throughout the continental US and into the Caribbean (Fig. 1). PARC is unique in that anyone and everyone can get involved,

FIG. 2. Timeline of major PARC activities and accomplishments, 1999–present.

regardless of their level of experience or expertise with amphibians or reptiles. To be a PARC member, the only requirement is a passion for the conservation of herpetofauna.

Another distinctive trait of PARC is that it is truly a bottom-up organization, where those in the field conducting scientific research, or those struggling with management challenges, come together to help provide expert-based guidance and conservation action at state, regional, or even national scales. We accomplish this primarily through our five Regional Working Groups and associated state chapters, which collectively form the foundation of PARC. These groups meet annually and identify amphibian and reptile conservation needs and goals. Goals identified then become projects or initiatives of Task Teams at the state or regional level, and some are carried forward via regional leadership to the Joint National Steering Committee. When multiple regions share the same priorities, their efforts are coordinated through National Task Teams.

Facts and Figures:
In its short history, PARC can attribute:

- Over **$4.1 Million** in grants and contributions that were directly related to PARC conservation activities and products.
  - Many of these grants also supported post-doctoral, doctoral, or master's degree student research.
  - Sources were primarily federal grant programs and direct contributions, including Landscape Conservation Cooperatives, Competitive State Wildlife Grants, Regional Conservation Needs (Northeastern US), National Park Service, US Fish & Wildlife Service, Bureau of Land Management, Department of Defense Legacy Resource Management Program, US Forest Service (USFS), and others.
  - Sources of cash and in-kind matching funds for these grants included numerous state fish and wildlife agencies and academic institutions, and other private and nongovernmental partners, such as The Orianne Society and the Amphibian and Reptile Conservancy (ARC).
- Over **184,000** hits to our jobs page since we relaunched our website in November 2010.
- Over **3600** "likes" on our national Facebook page, and many more on each regional page.
- Over **2000** subscribers to our listserv, which has evolved over the years into an announcement-only, informational list.
- Nearly **500** followers on our national Twitter handle, @PARCorg.

PARC's History, in Brief

PARC was established in 1999 to address widespread declines, extirpations, and range reductions of amphibians and reptiles primarily in the United States. Over 200 people attended the inaugural PARC meeting, including 40 representatives of academic and research institutions. PARC was created as the first and only network to focus on all native amphibians and reptiles, regardless of conservation status. We work proactively to benefit herpetofaunal populations before regulatory actions are required. Our intent is to "keep common species common." Because of PARC's inclusive nature, with respect to people as well as herpetofauna, we believe it to be the most comprehensive conservation effort ever undertaken for amphibians and reptiles.

As shown in Fig. 2, we have maintained steady growth overall since our inception. An increase in activity occurred starting in 2006, facilitated by an extended period with both of PARC's paid national coordinators in place (see below). The two coordinators were able to work together to initiate issue-driven conferences and training workshops, begin identifying strategic directions for PARC, and support the regional working groups that were seeking to achieve structure and stabilization. Although there has been occasional turnover among the two coordinator positions, both are filled currently, and we are again experiencing another burst of activity as an organization.

Our 2007 international conference, "Amphibian Declines and Chytridiomycosis: Translating Science into Urgent Action" convened over 200 participants representing nine countries across four continents, including 68 attendees from academic research institutions. We held our 2010 and 2013 roads and energy symposia, respectively, at the Joint Meetings of Ichthyologists and Herpetologists. In 2014, our "15 and Forward" symposium at The Wildlife Society annual conference celebrated PARC's 15 years of growth and accomplishments; interactive sessions helped identify potential areas of improvement and future directions.

The PARC Organization

Joint National Steering Committee.—The 21-member governing body of PARC with representatives from each of five regional working groups, external advisory committees, the national chairs and coordinators, and three at-large members representing industry, zoos, and nongovernmental organizations (Fig. 3) (Table 1).

External Advisory Committees.—The chairs of two external advisory committees serve on PARC's Joint National Steering Committee.

Federal.—Eleven (11) federal natural resource and land management agencies are represented on PARC's Federal Agencies

Fig. 3. The PARC organizational structure. Arrows depict the general flow of communication. Regional working groups form the foundation of PARC, driving up priorities and issues via their regional co-chairs to the Joint National Steering Committee (JNSC), the governing body of PARC. These co-chairs as well as the co-chairs of the external advisory groups, and at-large members, sit on the JNSC. Staffing is provided by two National Coordinators.

TABLE 1. Membership of the Joint National Steering Committee, the governing body of PARC, as of December 2015. Regional leadership elections occur at regional working group meetings, and national leadership elections occur each Spring.

Name	Affiliation	PARC Role
JJ Apodaca	Warren Wilson College, North Carolina	National Co-chair
Kristin Stanford	Ohio Sea Grant and Ohio State University Stone Lab	National Co-chair
Jen Williams	PARC, Colorado	National Coordinator, federal agencies
Priya Nanjappa	Association of Fish & Wildlife Agencies/PARC, DC	National Coordinator, state agencies
Alex Novarro	University of Maryland	Communication Specialist
Rob Lovich	US Naval Facilities Command, Southwest, California	Federal Agencies Steering Committee Co-chair
Casey Burns	Bureau of Land Management, Alaska	Federal Agencies Steering Committee Co-chair
Patty Riexinger	New York Department of Environmental Conservation	AFWA Amphibian & Reptile Subcommittee Chair
Eric Gardner	Washington Department of Fish and Wildlife	AFWA Amphibian & Reptile Subcommittee Vice-chair
Erica Hoaglund	Minnesota Department of Natural Resources	MW PARC Co-chair
Mark Jordan	Indiana-Purdue University, Fort Wayne	MW PARC Co-chair
Kathy Gipe	Pennsylvania Fish and Boat Commission	NE PARC Co-chair
Brian Zarate	New Jersey Department of Environmental Protection	NE PARC Co-chair
Kris Kendell	Alberta Conservation Association	NW PARC Co-chair
Betsy Howell	US Forest Service, Washington	NW PARC Co-chair
Andrea Drayer	Eastern Kentucky University	SE PARC Co-chair
Tom Gorman	Virginia Tech	SE PARC Co-chair
Michelle Christman	US Fish and Wildlife Service, New Mexico	SW PARC Co-chair
Clint Henke	ERO Resources, Colorado	SW PARC Co-chair
Jessica Homyack	Weyerhaeuser, North Carolina	At-large Member, Industry
James Lewis	Amphibian Survival Alliance, Virginia	At-large Member, NGO
Steve Olson	Association of Zoos and Aquariums, DC	At-large Member, Zoos
Jeff Holmes	Amphibian and Reptile Conservancy, Tennessee	ARC representative, Ex-officio
Ed Christoffers	Amphibian and Reptile Conservancy, Pennsylvania	ARC representative, Ex-officio
Linda Weir	US Geological Survey, Maryland	Past National Co-chair, Ex-officio
Polly Conrad	Utah State University	Past National Co-chair, Ex-officio

Steering Committee (FASC). These agencies are signatories to a PARC Memorandum of Understanding, established in 2001 and renewed every ten years, which formalizes their support and participation in the organization.

State.—States are represented in PARC via the Amphibian & Reptile Subcommittee of the Association of Fish and Wildlife Agencies (AFWA), which is a coordinating entity for all state and territorial fish and wildlife agencies in the United States and Canada. The subcommittee was established in 2008.

Regional Working Groups.—These groups are the foundation of PARC, where most of our members began their involvement. The Northeast (www.northeastparc.org) and Southeast (www.separc.org) are the oldest of the five regional working groups (regions), having initiated annual meetings in 1999 and 2000, respectively, shortly following PARC's first organizational meeting. The Midwest (www.mwparc.org) and Southwest (www.swparc.org) regions were initiated in 2002, and began regular annual meetings in 2006 and 2007, respectively. The Northwest region began meeting in 2008, and in the following year, expanded into western Canada. In 2013, the Southeast region expanded into the Caribbean.

Multiple examples exist in each region of people who became connected with PARC as undergraduate or graduate students, often due to involvement and encouragement by their professors to attend regional PARC meetings. In turn, many students have risen into leadership roles within PARC. One such example is our current Joint National Steering Committee chair, Dr. JJ Apodaca (Professor of Conservation Biology, Warren Wilson College). JJ began attending Southeast PARC regional meetings as a first-year graduate student. He went on to become co-chair of that region, and now leads the PARC organization.

Among those who have chaired the regions or the national steering committee over the years, representatives have included:
- 20 from academic research institutions
- 10 from federal agencies
- 20 from state/provincial agencies
- 1 from industry
- 4 from zoos
- 3 from non-governmental organizations
- 6 from private consultancies

National Coordination.—There are two paid, national coordinators for PARC. The Federal Agencies Coordinator, Dr. Jen Williams, is the only full-time, paid national employee for PARC. The position is supported by the contributions of several federal agencies, and is term-limited to four years. However, efforts are underway to make this role a permanent, federal position, given the longevity of support and need for such coordination capacity among the federal agencies.

The State Agencies Coordinator, Priya Nanjappa, is the only other paid national employee for PARC. This position was initially devoted to PARC and herpetofaunal conservation, and was supported by state and nongovernmental sources and grants. However, due to various funding challenges, and to increase the stability of the position, the position portfolio was shifted. As such, 1/3 of Priya's time is spent in her PARC role while another 1/3 of her time is spent coordinating state agency amphibian and reptile conservation activities. The remaining 1/3 of her time is spent addressing invasive species policy (all taxa) for AFWA. The position is now funded by a variety of state, federal, and private sources.

Both Jen and Priya address general national PARC coordination, including conference and symposia development, implementation of national priorities, and serving as national points of contact for PARC. These duties are in addition to specific projects and tasks for federal and state agencies, respectively. The federal position is currently hosted by the National Park Service in Fort Collins, Colorado, while the state position is hosted by the Association of Fish and Wildlife Agencies in Washington, DC.

The Amphibian and Reptile Conservancy

The Amphibian and Reptile Conservancy (ARC) is a 501(c)(3) non-profit organization that supports amphibian and reptile conservation, and PARC activities. Originally named Friends of PARC, Inc., it was founded by former PARC leaders in November 2007 and received its non-profit, charitable organization tax status in 2009. Because PARC is not an incorporated entity, ARC serves as the fiscal sponsor for PARC, handling and distributing funds, fundraising, and managing grants. Staffed by two volunteer officers and managed by a board of eight directors, ARC's operations are supported by product sales and a modest amount from overhead from grant management, as well as from donations from partners and the general public. To learn more about ARC or to read their prior annual reports, visit www.amphibianandreptileconservancy.org.

Current and Future Conservation Programs and Projects

Priority Amphibian and Reptile Conservation Areas (PARCAs).—The concept of identifying geographic areas that are important for the survival of herpetofauna arose about the same time within the southeast, northeast and southwest regions. Given this broad interest, a national task team was formed in 2008 to develop criteria and an implementation plan, completed in 2012. In 2015, the PARC Joint National Steering Committee agreed to make the implementation of PARCAs a national priority for the next three to five years. Modeled in part on the successful Important Bird Areas concept, this effort aims to promote voluntary conservation actions through the identification of the most significant geographic areas important for herpetofauna. Determination of PARCAs is intended to be coordinated nationally, but implemented locally at the state or regional scale. PARCAs carry no regulatory authority; however, the goal is to encourage and incentivize habitat management, restoration, or acquisition actions to benefit amphibian and reptile populations. Shapefiles for PARCAs will be made available for download via the PARC website starting in 2016. Our hope is that these areas will help scientific and conservation communities leverage research and management activities within them.

Roads Task Force.—In 2015, Johns Hopkins University Press published the book, *Roads and Ecological Infrastructure*, part of their new book series with The Wildlife Society. This book was a direct result of the PARC National Roads Task Force, which was created to develop solutions and conservation strategies for passage, connectivity, collision, and other road-related issues for amphibians and reptiles, in partnership with transportation entities. The book offers the most current research and knowledge in maintaining ecosystem connectivity and natural ecological functions while minimizing road effects on animals, including herpetofauna, small mammals, and other small vertebrates. Support for this effort has been generously provided by the USFS, ACO Wildlife, and ARC.

Disease Task Team.—Several recent amphibian and reptile pathogens, such as *Batrachochytrium salamandrivorans* (*Bsal*), ranavirus, and snake fungal disease, have received significant attention for their threat to herpetofaunal biodiversity. To address these threats, PARC formed a disease task team in January 2015 composed of biologists, veterinarians, and wildlife managers from the United States, Canada, and Mexico, with the goal of facilitating and guiding communication, collaboration, and response to outbreaks of herpetofaunal diseases. The team has developed a website, created a handout on *Bsal*, started a regional list of professional contacts when new disease outbreaks occur, and supplied input on the North American response to *Bsal*.

Federal Agency Conservation Activities.—PARC's federal agency partners have voiced their need for, and interest in, receiving conservation and management guidance for amphibians and reptiles. Very few agencies have full-time, permanent herpetologist positions. Given this lack of herpetofaunal management and conservation capacity, they have been strong supporters, both financially and in an advisory role, for PARC to help meet federal agency information and capacity needs. In 2009, the Department of Defense (DoD) took a particular interest in elevating the profile of herpetofaunal conservation on their lands and initiated an agency-based subgroup, DoD PARC. In 2015, a DoD PARC Strategic Plan was officially approved and implementation is underway.

State Agency Conservation Activities.—Only about 1/2 of state fish and wildlife agencies have full-time herpetologists on staff, yet all states are charged with managing herpetofauna. In particular, states are charged with overseeing personal and commercial uses of herpetofauna. In 2000, Congress mandated states to develop State Wildlife Action Plans that identified species of greatest conservation need, and priority conservation goals and actions. With PARC starting around the same time, partnering to provide the latest scientific information that could aid the development of these plans was a natural fit. Over the years, PARC representatives have advised in the development and revision, and have developed products that would guide the implementation, of these State Wildlife Action Plans. One state that has been particularly innovative in developing their herpetofaunal conservation capacity is North Carolina. There, the coordinator of the state PARC chapter is a full-time, paid employee of the North Carolina Wildlife Resources Commission. The state coordinator and other chapter members work together on matters of herpetofaunal conservation and management.

Through the financial support and in-kind contributions of both state and federal agencies, PARC has developed several conservation projects for them geared toward their employees or toward conservation and management on their lands. We implement these projects using our network of scientific and topical

experts as authors, information resource providers, instructors, or project leads. The following are a subset of these existing and future resources:

- Habitat Management Guidelines regional book series
- Inventory and Monitoring recommended techniques manual
- Training workshops in
  - habitat management, and inventory and monitoring guidance
  - law enforcement, including basic species identification and handling
  - wetland restoration and creation, resulting in the restoration or creation of more than 40 wetlands since 2013
- Guidance for sustainable use of herpetofauna through regulatory measures
- Webinars on scientific research findings, and in basic herpetology
- Identification of PARCAs, and incentivizing conservation actions within them
- Climate vulnerability assessments of priority herpetofauna
- Coordinated sampling and surveillance for the *Bsal* fungal pathogen

Internships

Starting in 2014, PARC initiated internships geared toward students or others interested in assisting us in our communications, social media, and photo curation. Such opportunities for engagement become available periodically, and are excellent ways to network within our broad partnership, demonstrate leadership and initiative on a resumé, and, if desired, gain college credit.

Summary

Science is in everything that PARC does; the involvement of scientists and experts on species and conservation issues is what keeps our efforts current and useful. At the national scale, we tackle large, overarching issues, while at regional and state scales, we tackle more specific and focused issues. At all levels, there are opportunities for anyone, whether an undergraduate or graduate student or a tenured professor, to become involved or even lead in our conservation initiatives and focused projects.

The PARC connection to the 2015 SSAR meeting provided an opportunity for our colleagues who are not typically able to attend scientific meetings to hear talks on cutting edge research and to network with the SSAR community. The social events were especially enjoyable, with the chance to meet and talk with our herpetological heroes and rising stars alike. PARC members were greatly appreciative to SSAR for the opportunity to partner in the planning of the conference, particularly the time granted to PARC to present information about our activities during the plenary session, and also the space provided to create nontraditional, applied symposia. Many students approached PARC members throughout the meeting to say that they were previously unfamiliar with our organization and indicated an interest in becoming more involved.

The chance to reach so many budding and established herpetologists in one place was immensely valuable to PARC. We hope, following the meeting, SSAR members think of PARC more readily, and perhaps this article will further facilitate engagement from the SSAR community in the future. To participate in PARC meetings or activities, please visit our website (www.parcplace.org) for additional information, or contact our national coordinators, Priya Nanjappa (pnanjappa@fishwildlife.org) or Jen Williams (jen_williams@nps.gov). We look forward to further strengthening this important partnership with SSAR and hope you will join us at our upcoming regional and state chapter meetings. Likewise, we hope to see you all again as part of further PARC involvement in future SSAR meetings.

Acknowledgments.—We are deeply indebted to Joe Mendelson for the invitation to PARC to collaborate with SSAR on the 2015 meeting, and for his additional efforts to better connect our two organizations in the past few years. We also acknowledge Kraig Adler, Bob Aldridge, Aaron Bauer, Rafe Brown, Rich Glor, and Robert Hansen for their interest and assistance in including PARC as a co-sponsor of the 2015 SSAR meeting, leading to the development of this manuscript. We thank Kraig Adler, in particular, for the idea to create such an article, and suggestions for content as well as improvements to early drafts. We are appreciative to Linda Weir and Kristin Stanford for their ideas and insights in the development of this manuscript, and in planning content for the meeting. Our gratitude extends to Phillip deMaynadier, Bill Sutton, David Bender, and Danny Martin for their direct assistance in planning and coordinating some of the PARC symposia and events held at the 2015 SSAR meeting, and to Kimberly Andrews, Bob Brodman, Jason Daniels, Allison Sacerdote-Velat, John Moriarty, and George Pisani for their time and suggestions as part of the PARC-SSAR planning team. Valorie Titus was instrumental in coordinating items for, and overseeing, the PARC booth, and student volunteers Alex Novarro, Sarah Bailey, and Kiley Briggs provided excellent assistance during the PARC symposia with loading talks and timing speakers. Scott Hove provided us with excellent graphic design of the figures in this paper. Finally, we are grateful for the financial support provided by the Amphibian and Reptile Conservancy, and Jeff Holmes and Ed Christoffers in particular, toward the PARC events and speakers at the 2015 SSAR meeting.

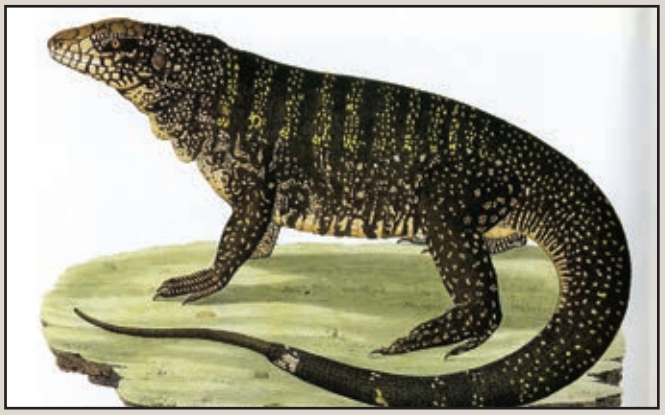
Studies on Lizards and Tuataras in Zoos and Aquariums. Part II—Families Teiidae, Lacertidae, Bipedidae, Amphisbaenidae, Scincidae, Cordylidae, Xantusiidae, Anguidae, Helodermatidae, Varanidae, Lanthanotidae, Shinisauridae, Xenosauridae, and Sphenodontidae

> The human imagination has never run as wild with lizards as it has with snakes; the familiar English expression "snake story" does not have its counterpart for lizards. Perhaps the one worldwide false belief about lizards is that they are venomous, and this belief is much harder to explain than the corresponding one about snakes. How could the presence of two poisonous lizards in sparsely inhabited parts of North America give rise to an interhemisperical belief that all lizards are dangerous? As a boy living in Georgia, I was taught to fear the little skinks (*Eumeces*) with their brilliant azure tails. The ominous name "scorpion" is applied to them there, to the confusion of many who know the scorpion as an invertebrate with a jointed, stinging tail. In tropical America, Africa, and Asia a general fear of lizards is often prevalent, and is based on the conviction that all are deadly.
>
> —Clifford H. Pope, *The Reptile World*, 1955

In Part I in the last issue of *Herpetological Review*, I included an introduction to the studies of captive lizards mostly in zoos and aquariums, history of lizards in these institutions, and lizard families Iguanidae, Agamidae, Chamaeleonidae, and Infraorder Gekkota**.** In this article (Part II), I continue with the rest of the lizard families and Tuatara.



Family Teiidae—At National Zoo, Hall (1978) documented husbandry, behavior, and breeding of Tegu lizards (*Tupinambis tequixin*) (Fig. 1.). McCrystal and Behler (1982) described husbandry and reproduction of captive Giant Ameiva (*Ameiva ameiva*) at New York Zoological Park. At Prague Zoo, Rehák (1999) bred the Guyana Caiman Lizard (*Dracaena guianensis*; Fig. 2.) and Denver Zoo has been successful in breeding this taxon. Three neonates hatched at the Shedd Aquarium in Chicago in 2005.

At the American Museum of Natural History in New York, Townsend (1979), Porter et al. (1994) and Townsend and Cole (1985) established colonies of parthogenetic whiptail lizards *Cnemidophorus* spp; a colony of parthenogenetic *C. exsanguis* reached seven generations. Tocidlowski et al. (1997) from North Carolina Zoological Park diagnosed teratoma in the Desert Grassland Whiptail (*Cnemidophorus uniparens*).

How could we have ever imagined that we would know precisely when a new species came into existence? Cole et al. (2014) described a new species called Neaves' Whiptail Lizard (*Aspidoscelis neavesi*). Their abstract: "The first known tetraploid amniote that reproduces through parthenogenetic cloning by individual females is named and described. The species originated through hybridization between *Aspidoscelis exsanguis* (triploid parthenogen) x *Aspidoscelis inornata* (diploid bisexual or gonochoristic species) in the laboratory." Future zoo record keeping for population managers or scientists who bank biomaterials is likely to be challenging—"Normally, new species are named not because they are newly formed but because they became recently known to science. In this case, *A. neavesi* really is a new species; its date of origin was August 12, 2008, when the first F_2 individual hatched."

Family Lacertidae—Herrmann (1998) from Cologne Zoo described reproduction in the East African Fringe-tailed Forest

JAMES B. MURPHY

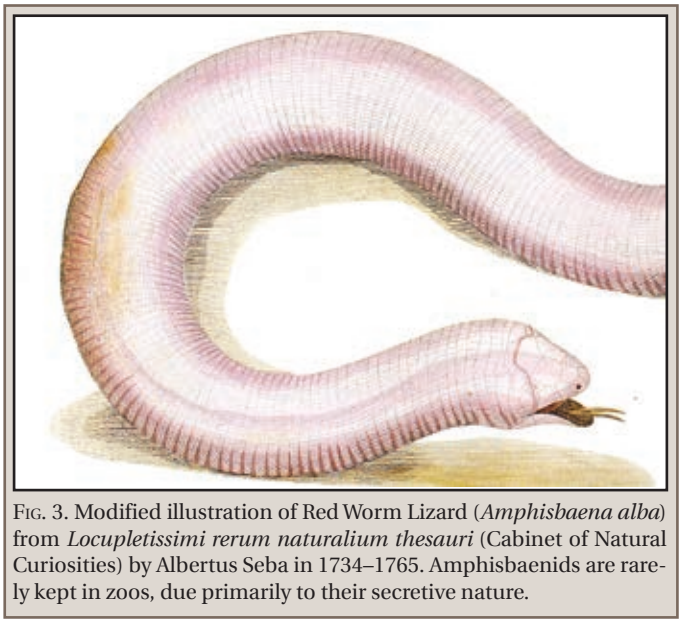
Fig. 1. Illustration of Common or Black Tegu (*Tupinambis tequixin*) by H. R. Schinz in 1833, *Naturgeschichte und Abbildungen der Reptilien*. Tegus remain popular zoo lizards, hardy, large, and showy.

SMITHSONIAN INSTITUTION LIBRARIES, WASHINGTON DC

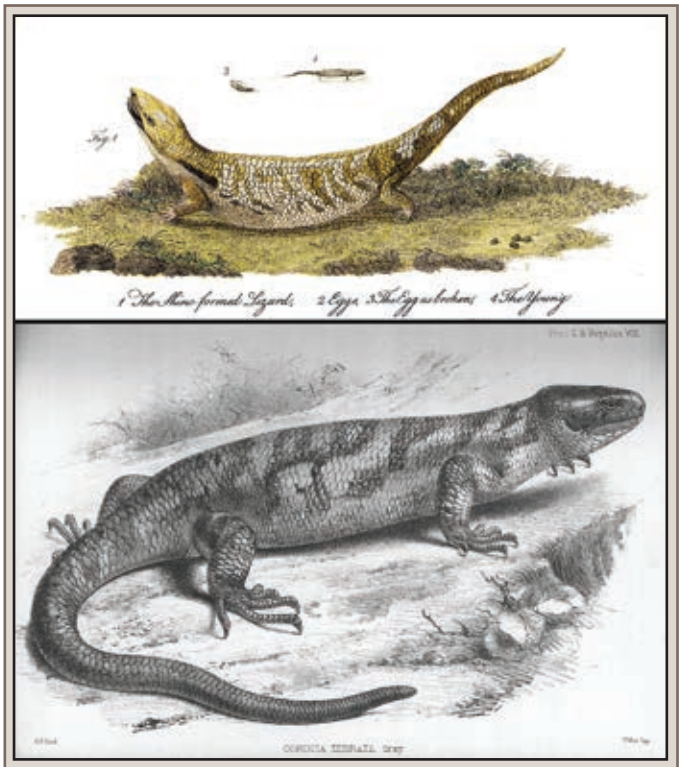
Fig. 2. Illustration of Caiman Lizard (*Dracaena guianensis*) in Baron Georges Cuvier's *Le règne animal…*, published in 1836–9. This lizard easily crushes large snail shells, which compose a significant part of the diet.



Lizard (*Holaspis guentheri laevis*). Avery (1994) discussed "shuttling thermoregulatory behavior" in two European lacertid lizards: *Lacerta vivipara* and *Podarcis muralis*. Cooper (1958) published observations on the eggs and young of the Wall Lizard (*Lacerta muralis*). Mendyk and Agragna (2014) described two introduced populations of the Italian Wall Lizard (*Podarcis siculus*) on Staten Island, New York. Rehák (2015) from Prague Zoo, Czech Republic, described the program for protecting and managing the European Green Lizard (*Lacerta viridis*).

Family Bipedidae—Jonathan Campbell brought a number of Four-toed Worm Lizards (*Bipes caniculata*) from Mexico to Dallas Zoo and they were hardy captives but insisted on burrowing so they were kept in jars with substrate in the rear section where they were off-exhibit. They fed avidly on small insects such as crickets, sarcophagid fly larvae, and mealworms (*Tenebrio*). Shaw (1962) wrote an article on the genus in the San Diego Zoo publication named ZOONOOZ, which can be turned upside-down but remains the same.

Family Amphisbaenidae—The only amphisbaenian I have seen on exhibit were several adult Red Worm Lizards (*Amphisbaena alba*) in the late 1960s at Fort Worth Zoo (Mehrtens 1962; Fig. 3.). John Mehrtens (pers. comm.) said they were hardy captives and showed no inclination to burrow out of sight. They were always visible every time I visited. The diet was a variety of insects and spiders.



Family Scincidae—At London Zoo, the first New Guinea Blue-tongued Skinks (*Tiliqua gigas*) were purchased on 17 June 1852 and gave birth to 27 neonates between 1866 and 1893 (Coote, 2001). Carpenter and Murphy (1978) saw tongue displays directed toward conspecifics by the Common or Australian Blue-tongue Skink (*Tiliqua scincoides*) at Dallas Zoo (Fig. 4, top). Tschambers (1949) from Brookfield Zoo documented birth of this lizard. Schildger and Wicker (1987) used endoscopic gender determination in the Shingleback Skink (*Tiliqua rugosa*) at Frankfurt Zoo (Fig. 5.). Schneider (1941) described fat storage in the tails of helodermatids and *T. rugosa*. The Melbourne Zoo sent a group of Shingleback Skinks to Dallas Zoo. We were interested in the intriguing reports on mate fidelity (over ten consecutive years) being published by C. Michael Bull and associates (1987, 1988, 2000). Our group was comprised of both sexes but we never saw male-male combat, courtship or copulatory behavior, much less evidence of monogamy. Our lizards thrived although one problem was the difficulty of shedding skin on digits, even when maintained on a rough substrate. The skinks had to be soaked in water and stuck skin manually removed with tweezers. If humidity was increased to try to prevent this problem, dermal lesions mostly on the dorsum began to develop.

Honegger (1975, 1985) from Zürich Zoo detailed the management and biology of the Prehensile-tailed Skink (*Corucia zebrata*). Groves (1994) described husbandry and reproduction of the colony of skinks at Philadelphia Zoo. Wright (1992, 1993) and Wright and Skeba (1992) explored husbandry and medical management of this skink at the Zoo. At Dallas Zoo, the skinks climbed the smooth metal shafts of snake hooks held in a vertical plane—a truly remarkable show of strength (Fig. 4, bottom). These hooks were slightly over four feet in length and constructed with aluminum golf club-shafts. When lifted on the hook, all lizards would start climbing the shaft until the handle was reached. If the hook was reversed, the lizards began moving again toward the top. The tails were very loosely coiled around the shaft; movement was accomplished by gripping the shaft tightly with three feet and extending one foreleg to move ahead.

SMITHSONIAN INSTITUTION LIBRARIES, WASHINGTON DC

FIG. 3. Modified illustration of Red Worm Lizard (*Amphisbaena alba*) from *Locupletissimi rerum naturalium thesauri* (Cabinet of Natural Curiosities) by Albertus Seba in 1734–1765. Amphisbaenids are rarely kept in zoos, due primarily to their secretive nature.

SMITHSONIAN INSTITUTION LIBRARIES, WASHINGTON DC

FIG. 4. Two of the largest skinks on the planet are pictured here. Top: Illustration of Eastern Blue-tongued Skink (*Tiliqua scincoides*) from *Journal of a Voyage to New South Wales with Sixty-five Plates of Non Descript Animals…* by John White (1790). This lizard displays its dramatic blue tongue toward conspecifics. Bottom: Prehensile-tailed Skinks (*Corucia zebrata*) from Solomon Islands and Papua New Guinea are incredibly strong. These skinks can climb the smooth metal shafts of snake hooks with aluminum golf club-shafts held in a vertical plane. Illustration from J. E. Gray's *New genus of fish-scaled lizards* (*Scissosaurae*) *from New Guinea* (1855).

Preserved lizards were scanned by a technician at University of Texas at Arlington with SEM to see if there were morphological adaptations to palmar or plantar surfaces—none could be located.

COURTESY OF JOHN EDWARDS

FIG. 5. London Zoo keeper with Shingle-back Skinks (*Tiliqua rugosa*) between 1872–1890. These lizards develop permanent pair-bonds (social monogamy) for up to 10 years.

SMITHSONIAN INSTITUTION LIBRARIES, WASHINGTON DC

FIG. 6. Modified image of Zonure (*Cordylus giganteus*) from Andrew Smith's *Illustrations of the Zoology of South Africa* (1838–1849). He was one of the first to include backgrounds in his illustrations.

Bloxam (1976) discussed maintenance and breeding of the Round Island Skink (*Leiolopisma telfairii*) at Jersey Wildlife Preservation Trust. Russell (1996) explored the natural history, captive husbandry, and reproduction of Crocodile Skinks (*Tribolonotus gracilis)* at Dallas Zoo. Morley (1992) reproduced the Narrow-banded Sand Swimmer (*Eremiascincus richardsoni*) and Post (2000) outlined captive husbandry and reproduction of the Hosmer's Skink (*Egernia hosmeri*) at Adelaide Zoo. Dathe and Dedekind (2002) reproduced Fire Skinks (*Riopa fernandi*) in Berlin Tierpark. At Dallas Zoo, a group of adult Schneider's Skinks (*Eumeces schneideri*) was on display for many years; the lizards were large, dramatic, attractive, and not secretive. Curator E. G. Boulenger (1920) from London Zoo discussed the Cylindrical Skinks (genus *Chalcides*). His father George A. Boulenger from British Museum described Armitage's Cylindrical Skink (C. *armitagei*) living in the Society's Gardens (1922).

At Dallas Zoo, three species of skinks were kept outdoors throughout the year in a massive exhibit with a hibernaculum and numerous rock crevices. The enclosure was heavily planted with cacti and succulents, mostly collected in southwest Texas. There were many other species in this exhibit such as chuckwallas, whiptails, side-blotched lizards, and fence, spiny, and sagebrush lizards. The three skinks were Five-lined Skink (*Plestiodon fasciatus*), Great Plains Skink (*P. obsoletus*) and Broadhead Skink (*P. laticeps*). All three skink neonates have vivid blue tails and each year, the exhibit would be filled with them darting through the rocks, constantly lifting and waving these tails. We assumed that this was an anti-predator behavior used to distract threatening enemies or demonstrate fitness. As the lizards matured to adulthood, the body and tail colors became muted and the skinks discontinued the tail-waving behavior.

Family Cordylidae.—Knowsley Park (1834–1851), the home of the Earls of Derby, housed the giant or Lord Derby's girdled lizard (described as *Zonurus derbianus*, now known as *Cordylus giganteus*; Figs. 6, 7.) (Keeling, 1984). At Dallas Zoo, we kept this lizard successfully. Another large African mixed exhibit there included many active and hardy lizards, exceedingly popular with visitors: Lesser Flat Lizard (*Platysaurus guttatus*), Drakensberg Craig Lizard (*Pseudocordylus subviridis*), Armadillo Girdled Lizard (*Cordylus cataphractus*); some Large-scaled Snake Lizards (*Chamaesaura macrolepis)* spent most of the time resting in tufts of grass. The enclosure had many rocky crevices and multiple basking spots.

Clay Garrett, one of my employees at Dallas Zoo, surprised me by naming a new species of *Eimeria* (Apicomplexa) from our *Cordylus cataphractus* from Namaqualand, South Africa after me (Upton et al. 1993).

Family Xantusiidae.—Holmback (1984) discovered parthenogenesis in the Central American Night Lizard (*Lepidophyma flavimaculatum*) at San Antonio Zoo. At Dallas Zoo we received a group of Desert Night Lizards (*Xantusia vigilis*) and Granite Night Lizards (*X. henshawi*) as food lizards from a California supplier but the keepers wanted to keep them as pets instead—they said that these creatures were too adorable to feed to other lizards. Receiving a stay of execution, they lived for years.

Family Anguidae.—Lawler and Norris (1980) bred the Haitian Giant Galliwasp (*Diploglossus warreni*) at Knoxville Zoo and over 300 offspring have been produced at the Nashville Zoo since 2000. One Central American Giant Galliwasp (*Diploglossus monotropis*) hatched at Nashville Zoo in 2005. Claffey and Johnson (1983) reproduced the Sheltopusik (*Ophisaurus apodus* now *Pseudopus apodus*) at Metro Toronto Zoo (Fig. 8.).

At Dallas Zoo, we successfully kept two species of *Abronia*: Mixtecan Arboreal Alligator Lizard (*A. mixteca*) and Martin del Campo's Alligator Lizard (*A. martindelcampoi*); and Imbricate Alligator Lizard (*Barisia imbricata*). They were kept at ca. 72°F (22°C) ambient temperature with a basking spot. Ardell Mitchell at Dallas Zoo collected the holotype of a new *Abronia* from Mexico, later named Mitchell's Arboreal Alligator Lizard (*A. mitchelli*) in his honor by Jonathan Campbell. Campbell collected an original series of a new *Abronia* in Jalapa, Guatemala, described by Edmund Brodie and Ron Savage as *A. campbelli* in 1993. This taxon is seriously endangered, likely close to extinction. The late John Werler, director of Houston Zoo, published several papers on *Abronia* and other lizards: Werler (1951, 1970) and Werler and Shannon 1961 (description of *Abronia reidi* and

FIG. 7. Girdled-tailed Lizards (*Cordylus giganteus*) on exhibit at Smithsonian National Zoological Park in Spring 1934. Charles R. Knight (1874–1953) was a famous artist, known for his paintings of prehistoric creatures such as dinosaurs and extant wildlife in museums, colleges, books, stained-glass windows, calendars, and other venues. He painted murals, backgrounds in animal enclosures, and animals at several zoos—Brookfield, Lincoln Park, National, and Bronx Zoos. This habitat painting in the Zonure display was one of many commissioned for the Reptile Building at National Zoo in the early 1930s. Unfortunately, these paintings deteriorated over time and were replaced three decades later. The bison on the 1901 US ten-dollar bill was drawn by Knight.

SMITHSONIAN INSTITUTION LIBRARIES, WASHINGTON DC

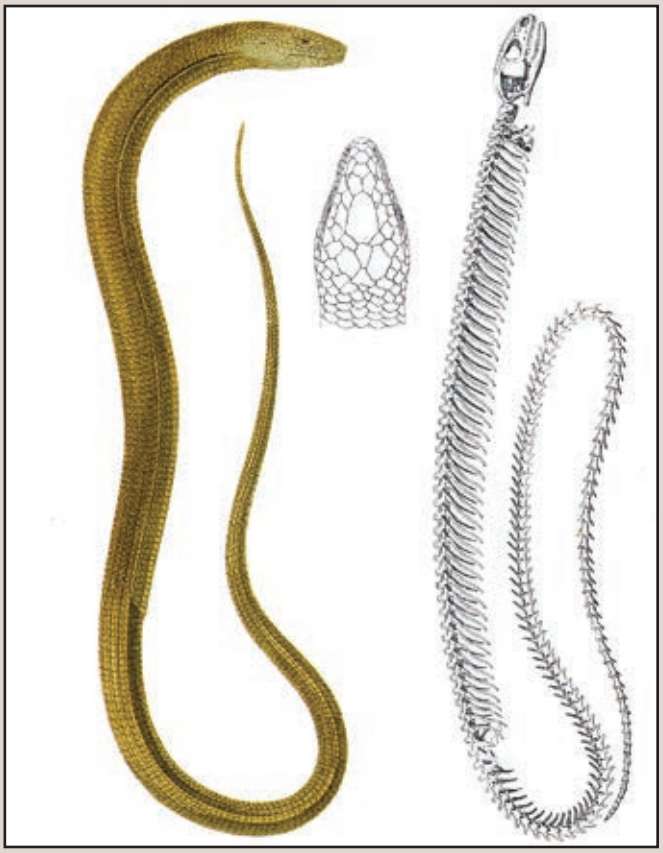

FIG. 8. Illustration of European Glass Lizard or Sheltopusik (*Ophisaurus apodus*) in Baron Georges Cuvier's *Le règne animal…*, published in 1836–1839. These hardy lizards are excellent zoo exhibit reptiles. Visitors often believe that these reptiles are snakes.

Xenosaurus sanmartinensis). He also published a paper with Jonathan Campbell in 2004 naming Ingrid's Galliwasp (*Diploglossus ingridae*) in honor of his late wife, Ingrid. One of the most interesting lizards displayed at Dallas Zoo was a small group of Madagascar Girdled Lizards (*Zonosaurus madagascariensis*). These lizards were attractive, active, and hardy in captivity. They regularly basked at high temperatures under a "hotspot" (100°F, 38°C) in a thermal gradient and fed mostly on insects rather than fruits and other vegetation.

At Dallas Zoo, we kept two species of the genus *Elgaria*: Arizona Alligator Lizard (*E. kingii nobilis*) and California Alligator Lizard (*E. m. multicarina*). Both were hardy captives and reproduced at the zoo but were likely impregnated in the wild when collected in autumn. These lizards can store sperm until eggs are fertilized. A live adult Texas Alligator Lizard (*Gerrhonotus liocephalus*) was found by a visitor in a wooded park next to a railroad track situated across the road to the front entrance of Dallas Zoo which was unusual as this is not within the range for this species. Jon Campbell said that there are no other records from Dallas and suggested that it surely escaped from our insecure collection.

Observations on the rare gerrhonotine *Coloptychon rhombifera* were made on captives at Parque Reptilandia, near San Jose, Costa Rica (Lamar et al. 2015). Neonates are spectacularly colored with bold black and white bands that become muted and the dorsum nearly patternless as the lizard ages. As this species is likely arboreal with a long prehensile tail, the eyes are oriented downward. Insects comprise the bulk of the diet, especially katydids which are a favorite food item. It moves in a snake-like, undulating fashion with limbs adpressed to the body.

Family Helodermatidae.—Murphy (2014) has covered these lizards recently in a review article.

Family Varanidae.—Horn and Visser (1989) reviewed reproduction of 20 spp. of monitor lizards in captivity and data on the biology of monitors (1991). The same authors (1997) provided an updated account which covered behavior, diet, egg incubation, light, reproduction, sexing, and taxonomy. Winston Card from Dallas Zoo and Arnold Kluge discussed hemipeneal skeleton and varanid lizard systematics (1995) and Card (1994) reported on the reproductive history of monitors at Dallas Zoo. Robert Mendyk and associates have discussed reproduction, mortality and longevity. Several reference books cover monitor lizards: Bennett 1998, Hutchins et al. 2003, Pianka et al. 2004. A survey on thermal requirements was published by Mendyk et al. (2014). An impressive and informative contribution for varanid biologists is

SMITHSONIAN INSTITUTION LIBRARIES, WASHINGTON DC

FIG. 9. Illustration of Le Varan à deux bandes (*Varanus bivittatus*, now *V. salvator*) in Alfred E. Brehm's *Les Merveilles de la Nature. Les Reptiliens et les Batraciens* in 1885. Robert Mertens considered the Philippine taxon (*nuchalis*) to be a subspecies of *salvator* in his varanid monograph in 1942. Now elevated to specific status, it is rare in captivity—I have only seen one specimen at the Berlin Zoologischer Garten's Aquarium Unter den Linden in 1969.

SMITHSONIAN INSTITUTION LIBRARIES, WASHINGTON DC

FIG. 10. Dumeril's Monitor *(Varanus dumerili)* from *Verhandelingen over de natuurlijke geschiedenis der Nederlandsche overzeesche bezittingen…"* by Salomon Müller (1839–1844). The newly hatched neonates are dramatically colored with a bright red head and black body with yellow-white bands.

SMITHSONIAN INSTITUTION LIBRARIES, WASHINGTON DC

FIG. 11. Desert Monitor (*Varanus griseus)* from *Symbolae Physicae-Zoologica,* by Christian Gottfried Ehrenberg (1828). This varanid is at risk, due primarily to habitat alteration and is listed in CITES Appendix I.

SMITHSONIAN INSTITUTION LIBRARIES, WASHINGTON DC

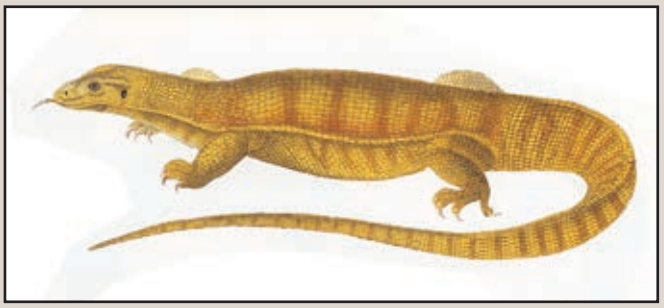

FIG. 12. Illustration of Yellow Monitor (*Varanus flavescens*) from *Illustrations of Indian Zoology Chiefly Selected from the Collection of Maj.-Gen. Hardwicke* by John Edward Gray (1830–1835). The species is listed in CITES Appendix I.

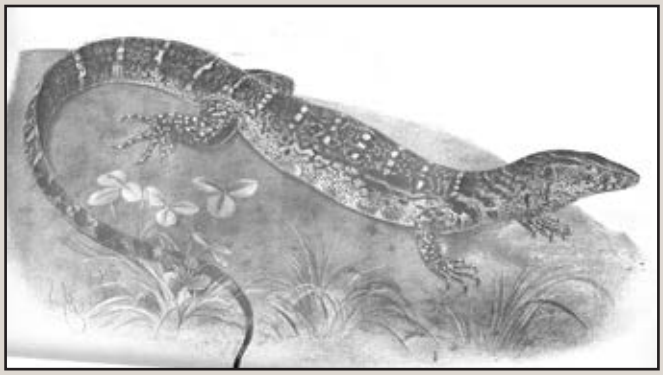

FIG. 13. Illustration of Nile Monitor (*Varanus niloticus*) from John Anderson's *Zoology of Egypt Volume First. Reptilia and Batrachia* (1898). A tame one was used for demonstrations at Dallas Zoo.

Biawak—Journal of Varanid Biology and Husbandry, an on-line journal edited by Robert Mendyk.

There are a number of accounts of Indo-Australian monitor lizards. Murphy (1971, 1972) provided data on Indo-Australian varanids at Dallas Zoo. Stirnberg (1997) described care and breeding of the Australian Lace Monitor (*Varanus varius*) in Bochum Zoo which led to 2nd generation offspring. Christie (1982) successfully introduced three incompatible male lace monitors at Indianapolis Zoo. Male Pygmy Mulga Monitors (*V. gilleni*) embraced conspecifics in an arching posture during combat rituals at Dallas Zoo (Murphy and Mitchell, 1974; Carpenter et al., 1976) and later Boyer and Lamoreaux (1983) bred this species there. Seemingly irrelevant behaviors can sometimes occur.

Dominant Pygmy Mulga Monitors treated subdominants as females after male-male combat. The loser became immobile and allowed the winner to mount and initiate pre-copulatory behaviors (Radcliffe and Murphy 1983). Irwin (1994) reported on the behavior and diet of the Queensland Tree Monitor (*V. teriae*) at Queensland Reptile and Fauna Park (now Australia Zoo). Gaikhorst et al. (2009) bred Mitchell's Water Monitor (*V. mitchelli*) at Perth Zoo. Brotzler (1965) outlined Mertens' Water Monitor (*V. mertensi*) breeding in Wilhelma Zoo (Stuttgart). In 2005, this taxon reproduced at Wildlife Conservation Society. Murphy and Lamoreaux (1978) saw dramatic bipedal threatening behavior in Mertens' water monitor directed toward other large iguanid lizards at Dallas Zoo. The varanid compressed its body laterally with gular extension. At National Zoo, this semi-aquatic species used its body and tail to herd live fishes in order to trap them in shallow water. Its body was moved parallel to the side of the pool which was rocky around the perimeter and the monitor used its tail in small radius bends to block openings between the rocks. When the fishes were trapped with no avenue for escape, the monitor turned its head posteriorly but kept body and tail in place, and grabbed some of them in mid-air as they tried to jump over the lizard (pers. observ.). Mitchell (1990) reported on reproduction of Gould's Monitors (*V. gouldii*), Garrett et al. (1996) compared chemosensory behavior and prey trail-following in the varanoid lizards *V. gouldii* and *Heloderma suspectum,* Doles and Card (1995) discussed delayed fertilization, and Card (1994) reported double clutching in Gould's Monitors and Gray's Monitors (*V. olivaceus*) at Dallas Zoo. Walter Auffenberg deposited an adult male Gray's Monitor at this Zoo. He invited one of the zoo staffers to join him in the Philippines to help gather data for his intended book on this taxon. Another male and two females were collected and transferred to Dallas where the lizards easily adapted to captivity. We tried palm nuts, various fruits, terrestrial snails and other food items based on Auffenberg's analysis but all were mostly ignored except laboratory rats which were immediately consumed. Yuyek (2012) reported on husbandry and reproduction of *V. olivaceus* at Avilon Montalban Zoological Park in the Philippines. Stunkard and Gandal (1961) identified nematodes and cestodes from the Gould's Monitor. Irwin (1996) described courtship, mating and egg-deposition by the Perentie (*V. giganteus*) at Queensland Reptile and Fauna Park (now Australia Zoo). The Melbourne Zoo kindly sent two young pair of Perentie Monitors to Dallas and one hatched later. Eidenmüller and Wicker (1991) covered captive breeding, artificial egg incubation, development and surgical removal of impacted eggs in *V. timorensis similis* at Frankfurt Zoo.

We had several Crocodile Monitors (*V. salvadorii*) ranging in size from subadults to large adults at Dallas Zoo. I learned the hard way that the long tail is a potentially lethal weapon. When I was moving the largest one from the cage to the floor, it used its tail and accurately struck me in the face with the tip, just missing my eyes. Each time it aimed for my eyes and I took to using a welder's mask to protect myself. I noticed that all of these monitors had a frothy mixture of blood and saliva around the dental arcade. At first we thought that this was due to an infectious disease but found that many captives at other zoos had this same exudate and it was also present in published photographs. It would be interesting to compare this taxon with Komodo Dragons, which often are seen with long strands of saliva hanging from the mouth. Camina et al. (2013) described husbandry and breeding of the Crocodile Monitor in two zoos in Madrid, Spain.

Hartdegen et al. (1999) observed feeding behavior of the Black Tree Monitor (*V. beccarii*) at Dallas Zoo. One interesting feature was the use of permanent prey killing sites on horizontal branches, much like raptors. Mendyk and Horn (2011) described forelimb movements and extractive foraging in this lizard. Kuppert (2013) described this unique feeding strategy in the closely related arboreal Green Tree Monitor (*V. prasinus*) at National Zoo—"… drill holes in a thick branch. The openings should be small and long enough so that the monitors cannot stick their snouts into an opening. But they must be large enough for them to reach inside with their forelimbs to extract food. It is important that the holes are drilled neatly, so that the lizards cannot injure themselves. The lizards will be able to smell the food, but not necessarily see it… Once the prey item was detected by smell or by sight, both lizards tongue-flicked around the opening to investigate its content, then stuck their snouts in the opening, only to discover that the food was out of reach. After the unsuccessful attempt with their snouts, they reached into the hole with a forelimb while maintaining eye contact with the food. The prey was hooked with the claws, extracted, and consumed. Extraction of food items out of a small opening requires highly coordinated movements of the wrist and the digits." At Dallas Zoo, this lizard would wrap the tip of its prehensile tail and drop the body from the perch and snatch prey off the substrate (see Greene 1986). Shuter (2014) described a novel underwater foraging behavior observed in *Varanus prasinus* at the Wildlife Conservation Society's Bronx Zoo; the lizard kept its eyes closed and tongue-flicking was not observed while submerged as it probed crevices for prey.

Müller (1970) bred the Water Monitor (*V. salvator*) at Leipzig Zoo (Fig. 9), David (1970) at the Ahmedabad Zoo, and Hairston and Burchfield (1992) at Gladys Porter Zoo in Brownsville, Texas. Herrmann (1999) documented husbandry and captive breeding of the water monitor in Cologne Aquarium at the Zoo. Honegger and Heusser (1969) contributed an analysis of the behavior inventory of the Water Monitor. Davis et al. (1986) recorded ritualized combat in captive Dumeril's Monitors (*V. dumerili*; Fig. 10). I saw a film of an adult Dumeril's Monitor attacking a large crab and it was grisly. The lizard began by pulling off both pinching claws, then removing each leg until only the carapace remained. Each part was quickly ingested. The crab was still alive but finally died when the monitor crushed it in its jaws and swallowed it piecemeal. Judd et al. (1977), Morris and Alberts (1996) and Morris et al. (1996) explored sex determination in the Komodo Dragon (*V. komodoensis*) and White-throated Monitor (*V. albigularis*) at San Diego Zoo.

When I was in college, I spent much time with the late George McDuffie who was a rather portly eccentric high school biology teacher in Cincinnati, Ohio. He was known throughout the region for his encyclopedic memory, evidenced by his ability to recite hundreds of limericks—mostly unacceptable in polite society—and his total lack of fashion sense, proven by the abundance of food stains and his collection's fecal matter on his clothing. Most of his garish mismatched garments appeared to be purchased for a paltry sum at a garage sale. One early evening, parents were invited to meet with him in his classroom to discuss academic progress or lack thereof related to their teenagers. Being a misanthrope, George found the whole exercise unpleasant and unproductive but his superiors insisted that this bonding be done with a positive attitude. This room was filled with tame crocodilians, tegus, rhino iguanas, water monitors, tortoises, an adult alligator snapping turtle with three legs and a cropped tail, and so on which were allowed complete freedom to traipse around

the room and rest under the desks of the students. During class, it was strange to see students resting limbs on the tops of large African spurred tortoise shells barely listening to his lectures or petting a two-meter alligator while taking a test likely to be failed. One large water monitor spent most of the time lying on the grate on top of the heater next to the window basking in the sun. I watched one elegantly-dressed mother move cautiously toward this immobile varanid until she was next to the head—clearly she thought it was dead and stuffed and wanted a closer look. The saurian flicked its tongue and the tines touched her face, causing her to jump backwards, scream loudly, and experience unanticipated micturition—she was mortified, quickly left the school without cleaning up her metabolic waste, and never returned for a future conference, according to George who found the episode most amusing. He told me that he had to figure a way to have this happen with all of the parents so he could be left in peace until retirement.

Perry et al. (1993) described the first captive reproduction of the Desert Monitor (*V. g. griseus*) at the Research Zoo of Tel Aviv University (Fig. 11). Visser (1981, 1985) provided notes on the breeding of the White-throated Monitor (*V. albigularis*) and Yellow Monitor (*V. flavescens*) in Rotterdam Zoo (Fig. 12). Monitors are known to be voracious feeders but, in a particularly strange instance, one *V. albigularis* ingested a metal fork used to feed it dog food (Hubbard 1996). Ferguson et al. (2009) used juvenile Black-throated Monitors to test the efficacy of dietary and UVB sources. Manrod et al. (2008) described rapid solving of a problem apparatus by juvenile Black-throated Monitors (*V. a. albigularis*). Barker (1984) reproduced Green Tree Monitors (*V. prasinus*) at Dallas Zoo and H. Bosch at Löbbecke-Museum + Aquazoo (1999). Davis (2014) successfully repaired a ruptured egg by using tissue adhesive at Bristol Zoo. Bosch also published on parasites in monitors (1999). Pauly (2007) diagnosed chronic stomatitis caused by an ectopic tooth in a Blue-tailed Monitor (*V. doreanus*) in Tierpark Berlin. One Black Tree Monitor (*Varanus beccari*) hatched at Buffalo Zoo in 2005. Radford and Paine (1989) hatched five Dumeril's monitors (*V. dumerili*) at Buffalo Zoo. Rehák (1996) followed the reproductive biology of the Mangrove Monitor (*V. indicus*) in Prague Zoo. Ziegler et al. (2010) reported upon the first F_2 breeding of the Quince Monitor Lizard (*V. melinus*) with conjoined dead twins at Cologne Zoo Aquarium. Ziegler et al. (2009) described the first captive breeding of the Blue Tree Monitor (*V. macraei*) at Plzen and Cologne Zoos. At Antwerp Zoo, van Dyjk (2007) trained the Nile Monitor (*V. niloticus*) and at Dallas Zoo, we used a completely tame adult for demonstrations for the visitors. This lizard allowed touching and petting, and thus was a perfect ambassador for varanid lizards (Fig. 13).

In 1942, Gustav Lederer, who redesigned the Aquarium and renamed it "Exotarium" after it was destroyed by Allied bombing at Frankfurt Zoo, published obervations on captive Komodo Dragons (*V. komodoensis*), including a photograph of a woman with a large dragon. Lederer discovered that dragons can recognize different humans and are able to distinguish one from another person. At this Zoo, the dragon knew the veterinarian after the second treatment and could no longer be persuaded to leave its hiding place as soon as the vet appeared. The lizard even recognized the operating table and fled from it (Lederer 1931). Murphy and Walsh (2006) recorded the surprising interactions between dragons and humans over time, many in zoo settings, "At the Dallas Zoo, Curator Ruston Hartdegen and associates have discovered that a dragon could discriminate between its permanent keeper, another reptile keeper who had less contact with the dragon, and a keeper from another animal department. The dragon was calm with the familiar caretaker, nervous around the less-familiar reptile keeper, and displayed defensive behavior to the keeper from another animal department (R. Hartdegen, pers. comm.). Kraken at National Zoological Park exhibited the same responses toward familiar and unfamiliar persons." Dragons have now been bred for three generations at Rotterdam Zoo but Visser et al. (2009) covered the issue of inbreeding. In this case, reproduction was not planned but four neonates suddenly appeared in a heavily-planted enclosure. Sunter (2008) described management and reproduction at London Zoo.

Murphy et al. (2002) investigated factors necessary for the captive management and conservation of these lizards and confirmed some of the Lederer observations. Komodo Dragons reproduced at National Zoo beginning in 1992 for the first time in any zoo in the Western Hemisphere, providing an opportunity to look at individual variation with a larger sample size. Four clutches were laid at the Zoo, resulting in 55 hatchlings. All but two hatchlings were tractable but those two individuals were aggressive toward humans for their entire lives. At the Zoo, an adult female named Kraken recognized the permanent keeper and researcher Trooper Walsh during trials to study play behavior; in only one instance did the lizard react in a threatening manner toward Trooper and that was when he was scratching its dorsum with his fingernails. The varanid immediately assumed an aggressive stance, extending the hyoid and compressing the body laterally. We interpreted this unusual response to a misreading of its dorsum being scratched as pre-copulatory behavior by a courting male, resulting in a rejection response. Kraken always reacted aggressively to another keeper in the department. A series of studies at National Zoo confirmed that Komodo Dragons indeed play with inanimate objects and interact with caretakers (Burghardt et al. 2002). Kuppert (2013) investigated olfaction and trail following behavior. Murphy (2014) discussed the recent research on dragon venoms and parthenogenetic reproduction. Hellmuth et al. (2012) used operant conditioning and desensitization to facilitate veterinary care with captive reptiles, including dragons at National Zoo. Since 1996, this species is listed in CITES Appendix I as vulnerable.

Chris Wemmer told me that many years ago, National Zoo herp keepers routinely fed dead animals from the collection after necropsy to reptiles. Head keeper Lee Schmeltz acquired a carcass of a muntjac that recently died in the collection and fed it to the Komodo dragon during visiting hours. The dragon seized the muntjac by the belly and tossed its head in a violent slashing motion which eviscerated the deer, splashing the glass front of the enclosure with blood, metabolic by-products, and entrails. Predictably, the incident was reported in record time to higher authorities and Schmeltz was warned never to let it happen again.

When the late Walter Auffenberg gave a talk at the Dallas Zoo's Zoological Society dinner, the topic was Komodo dragons. His book on them had been recently published and there was much interest. As we sat down for dinner, Walt showed a series of slides of dragons attacking live tethered goats and the bloody images were riveting. I figured that the vast majority of the attendees would be unable to finish their dinners but they munched away without pause as they sat staring at the graphic images. One fact was absolutely stunning: an adult female weighing 42 kg ate a wild boar carcass of 30 kg in 17 minutes; Walt's wry sense of humor was in evidence as he warned the diners not to overeat. Some years later, I went to Komodo Island and asked

the rangers if I could duplicate Auffenberg's earlier predation studies by finding several live goats to present to the dragons (see Auffenberg 1978). The Indonesian government had set aside a protected raised area for the tourists to watch dead goats being flung into a group of 20 lizards below several times a week. Ranging in size from large males to subadults, the dragons were habituated to this place in order to make an easy living. I was surprised that Timor deer and boar slowly moved and grazed quite near the lizards and these mammals were ignored. The rangers were willing to help with my observations but we could not figure out how to stake out live goats without risk to our well-being. Finally, we euthanized the goats as it simply was not safe to do otherwise. When the first young goat hit the ground to the point where not a single speck of goat other than a few tufts of hair and spilled stomach and intestinal contents were visible, I timed the episode—seven minutes! This was much faster than the timeframe I expected after reading the Auffenberg book and paper but I had counted the lizards beforehand so there were a lot of mouths operating simultaneously. Surprisingly, I never saw one dragon bite another even though they were side-by-side and vigorously tugging and tearing the carcass. The younger dragons were cautious, darting in to snatch a piece while the large ones were preoccupied with the goat. Young dragons are arboreal to avoid predation by adults. Later, one of the rangers tied a hind limb of a goat to a long rope and ran around to show how fast dragons could run. He was not running at sprinter's speed but fast enough, followed by a bunch of lizards. It reminded me of a pied piper leading a group of children. The rangers tied the goat hindquarters to a tree branch to demonstrate how the lizards could stand on their hind feet, using the tails to stabilize their bodies in three places when attempting to reach the meat. The lizards never tried to jump. Later I watched two large males of equal size stand bipedally, wrap the forelimbs around each other, and engage in ritualized combat until one was the clear winner—the struggle lasted ca. 15 minutes with no biting. The other quickly dashed away. Males courted and mounted females constantly but I never observed copulation. Females remained immobile beneath males.

The next day, I traveled to Rinja Island and watched a subadult dragon ca. one meter total length forage for two hours. The lizard thoroughly examined every branch, rock or other object, circling each possible site and directing rapid tongue-flicks under each if there was a gap beneath the object and ground. The foraging was unsuccessful. See Chiszar et al. (2009) on response of hatchling Komodo dragons at Denver Zoo to visual and chemical cues arising from prey. Later, I was walking on a dirt trail and heard an alarm call from a Timor deer. Fifteen minutes later an adult dragon ca. 2 meters slowly crossed the trail, ignoring me. The call was very loud and penetrating so I believe that the lizard made contact with the mammal but was unable to bring it down. This story does not have a happy ending. When the government decided to discontinue the feeding on Komodo so the lizards would act normally, many refused to leave the site and starved to death. Quentin Bloxam sent photographs to me documenting this saddening event (see Walpole 2001).

Pianka (1995) presented information on size differences in varanids. Body mass varied nearly five full orders of magnitude. In Australia, two major lineages have evolved extensive radiation: one evolved dwarfism (subgenus *Odatria*) and the other remained large (subgenus *Varanus*). Several evolved gigantism. When Arnold Kluge kindly placed an adult Short-tailed Pygmy Monitor (*Varanus brevicauda)* on loan to Dallas Zoo, we were

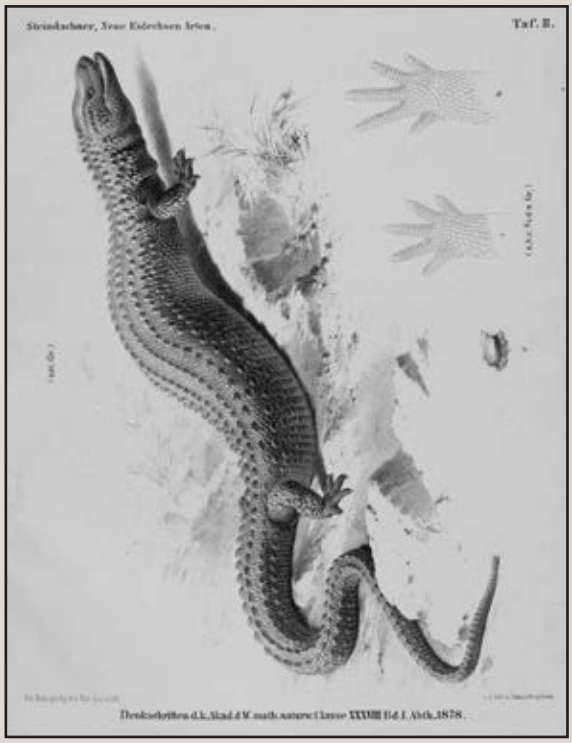

FIG. 14. Illustration of Borneo Earless Monitor (*Lanthanotus borneensis*) from Franz Steindachner's (1878) new species description in *Über zwei Eidechsen-Arten aus Süd-Amerika und Borneo. Denkschr. Kais. Akad. Wiss.* (*Wien*). Due to its rarity, only a few specimens have been kept in zoos.

able to show living examples of the World's smallest monitor and the largest (*V. komodoensis*).

Pianka and King (2004) wrote: "Recent experiments on captive *V. albigularis* by John Phillips at the San Diego Zoo suggest that some varanids can actually count. Lizards were conditioned by feeding them in groups of four snails in separate compartments with movable partitions, which were opened one at a time to allow monitors to eat each batch of four snails. Upon finishing the fourth snail, lizards were allowed into another chamber containing four more snails. After such conditioning, one snail was removed from some snail groups. Lizards searched extensively for the missing fourth snail, even when they had access to the next group. Similar experiments with varying numbers of snails showed that these varanids can count up to six, but with groups of snails larger than six, the monitors seemed to stop counting and merely classified them as "lots", eating them all before moving on to the next chamber (King and Green, 1999, p. 43)." King and Green (1999) concluded: "So it would seem goannas can count better than a lot of small children."

Family Lathanotidae.—The Borneo Earless Monitor (*Lanthanotus borneensis*) has been rarely kept in zoos, being seldom collected (Fig. 14). I have seen them at New York Zoological Society and Cincinnati Zoo. In both places, I was told that they were so secretive, they could not be exhibited. They fed on living fishes and earthworms, which the lizards located in the water with tongue-flicking. Most of the time, they remained soaking in the water dish. Three were also kept at San Diego Zoo off-exhibit, at least when I visited Chuck Shaw (see Shaw 1963). Robert Sprackland has created a recent Facebook page (https://www.facebook.com/lanthanotus) showing a neonate hatching in a Japanese zoo from an egg. The iZoo in Japan specializes in amphibians

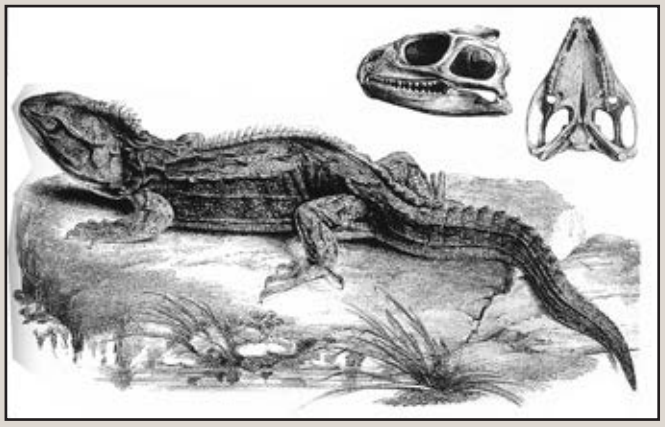

FIG. 15. Illustration of Tuatara (*Sphenodon punctatus*) in *The Lizards of Australia and New Zealand* by John Edward Gray (1867). He believed that this reptile belonged in the Family Agamidae.

and reptiles. Reproducing this species is a major accomplishment. There is a photo of the female surrounded by six eggs on the Zoo's website. Shirawa and Bacchini (2015) described captive maintenance and first reproduction.

Family Shinisauridae.—Visser (1989) and Kudryavtsev and Vassiliev (1998) reproduced the Chinese Crocodile Lizard (*Shinisaurus crocodilurus*) at the Rotterdam and Moscow Zoos, respectively. At Tiergarten Nürnberg, Germany, Mágdefrau (1997) described biology, sex determination using head morphology, care and breeding of this species. Whiteside and Garner (2001) found a thyroid adenocarcinoma in this lizard. During the past decade, zoos have been successful at reproducing this taxon. In early 2015, seven were born at Staten Island Zoo.

Family Xenosauridae.—In 2005, the San Antonio Zoo reproduced the Flathead Knob-scaled Lizard (*Xenosaurus platyceps*). We kept a group of *X. grandis* at Dallas Zoo but they did not reproduce.

TUATARA

> EVEN THE SPIRITS OF CHILDREN ARE SAID FREQUENTLY TO RETURN AS GODS, AND HEAL THE SICK WHO COME TO THEM. SOME YEARS AGO, A CHILD NAMED MATI WAS SAID TO HAVE THUS REAPPEARED ; NUMBERS WENT AND CARRIED THEIR SICK TO HIM ; HE ALWAYS TOLD THEM HE KNEW WHAT WAS THE MATTER WITH THEM—THEY HAD A LIZARD IN THEM , WHICH WAS THE CAUSE OF THE DISEASE ; OR, IF THE PERSON WAS VERY BAD, HE WOULD SAY HE HAD TWO OR MORE OF THESE REPTILES IN HIM ; AND IF EXTREMELY ILL, THAT HE HAD A GREAT RUATARA, OR GUANA [TUATARA], IN HIM ; THIS, OF COURSE, WAS VERY ALARMING TO THE FRIENDS OF THE SICK, WHO WOULD IMMEDIATELY ENTREAT THE GOD TO CAST IT OUT, WHICH HE READILY ENGAGED TO DO, ALTHOUGH SOMETIMES IT WAS STIPULATED BEFOREHAND WHAT REMUNERATION HE WAS TO RECEIVE ; HE THEN IMITATED THE SQUEAKING OF THIS LIZARD , AND TOLD THE PARTIES HE HAD EXPELLED THE REPTILE, AND THE PATIENT WOULD NOW SPEEDILY RECOVER.

> *TE IKA A MAUI, OR, NEW ZEALAND AND ITS INHABITANTS : ILLUSTRATING THE ORIGIN, MANNERS, CUSTOMS, MYTHOLOGY, RELIGION, RITES, SONGS, PROVERBS, FABLES, AND LANGUAGE…* BY RICHARD TAYLOR, 1870, P. 153.

When I was at Dallas Zoo, we began arrangements with the New Zealand government to receive a group of eight captive-hatched Tuatara (*Sphenodon punctatus*) from Stephens Island being held at the Wellington Zoo (Fig. 15). We worked with David Towns, a biologist who was a conservation researcher in country. One night he explained over a few beers how difficult it was to remove feral cats from these rocky islands—trapping, poisoning, shooting, and so on was ineffective. As there were no sandy beaches, one creative biologist suggested putting traps around sandboxes—amazingly, it worked beautifully and cats were removed. This was during a period when there were disagreements about who was responsible for overseeing New Zealand fauna and flora—the government or the Maori people (see Cree 2014:466–469 for an historical overview). This was a protracted exercise as there were many legal issues that had to be resolved. In the meantime, I asked Carl Gans (who had studied tuatara extensively), to share tips for keeping them successfully as he had one, which eventually was sent to the Saint Louis Zoo for breeding. I visited with curator Ron Goellner and director Charles Hoessle at the Zoo, asking advice for successful management. They kindly showed me the elaborate setup in the basement with sophisticated temperature devices since these reptiles would quickly deteriorate if kept too warm (see Goellner 1984).

After many months, the government agreed to send the animals to Dallas but an elder Maori husband and wife team would need to bless the enclosure beforehand. This was necessary as our zoo was one of the first to be granted permission to display tuataras by the New Zealand government; in the past, these reptiles had to be kept off-exhibit as stipulated by the government. When the couple arrived from New Zealand they were dressed in western clothing; they changed into traditional clothing for the blessing. This was a big event so the New Zealand government invited press and many dignitaries. It was a really nice ceremony and all guests were taken with the Maori prayers, chanting, songs, and best wishes for the well-being of the tuataras and caretakers. When finished, they changed back into their original garments in order to fly to Los Angeles to see their daughter at UCLA.

Later, Barbara Blanchard, a keeper from Wellington Zoo, accompanied the animals from New Zealand to Dallas and all went well. As we unpacked them at the Zoo, I remembered a story from Reverend Gregory Bateman (1897), "Some time ago, I was looking at the various animals in a very large dealer's establishment, when I made a remark about a fine pair of Tuateras which I saw in a big cage. The assistant who was with me immediately opened the door of the den and seized one of the reptiles by the tail, and I shall not readily forget the ominous sound made by the animal's closing jaws as he just missed the man's fingers, at which he had just snapped. I at once mentally resolved never to catch a Tuatera [sic] by the tail. As I congratulated the man upon his escape, he said, 'I am a bit lucky this time, for I have just come out of the 'orspital, where I have been laid up with blood-poisoning through the bite of one of them pythons.' " Later, we sent two specimens to Toledo Zoo but I cannot attest to their tractability.

Hick (1965) solicited comments by specialists of captive Tuatara held at the Auckland, Basel, Chester, Detroit, Dublin, Jersey, and San Diego Zoos. Austin (1962) described captive Tuatara at Detroit Zoo. Hoessle (1969) described the Tuatara display at St. Louis Zoo. Cree et al. (1994) highlighted the importance of captive management to the conservation of Tuatara in New Zealand. Goetz and Thomas (1994) used annual growth and activity patterns to assess management practices for captive Tuatara. Hartley (1963) described observations on Tuatara at Jersey Wildlife Preservation Trust. Lange (1997) outlined the husbandry and captive maintenance of 10 young Tuatara in Berlin Aquarium. Gillingham and Miller (1991) studied reproductive ethology and Gillingham et al. (1995) described social behavior. Keall et al.

(2010) described the use of artificial incubation with threatened populations.

Wood (1967) and Tintinger (1987) bred the Tuatara at Auckland Zoo. This Zoo has been involved in an important conservation program. Six of the last remaining Tuatara were removed from Cuvier Island (Repanga Island) between 1989 and 1991 for captive breeding. Thirty offspring have been produced which were returned to the island after rats were removed (Cree 2014). Newman (1982) offered suggestions for breeding Tuatara in captivity. The rare North Brother Island Tuatara (*Sphenodon guntheri*) are being produced in numbers from eggs incubated in captivity in New Zealand (Cree et al. 1994). Eight specimens were at San Diego Zoo in 2002 (Blanchard et al. 2002). Tuataras are now regarded as a single species (*S. punctatus*; Hay et al. 2010) but each island population should be maintained separately.

Liu and King (1971) described microsporidiosis in Tuatara at New York Zoological Park. Blanchard (1992) focused on management in the wild and in captivity. Boardman and Sibley (1991) covered captive management, diseases, and veterinary care of Tuatara, based on experiences at Auckland Zoo. Newman et al. (1979) used field observations to underscore their recommendations for captive maintenance. Two articles appeared in "Animal Kingdom," the publication of New York Zoological Society (Oliver 1953; Waddick 1973). See also Goetz and Thomas (1994), Terezow et al. (2008), and Wörner (2009).

An important book has just been published by Alison Cree, called *Tuatara*: *Biology and Conservation of a Venerable Survivor* (2014). Contents include biological, historical, cultural, and conservation topics. Major Stanley Smyth Flower (1925) had his final word, "That *Sphenodon* lives to fourteen years, and probably longer, is a fact of interest." Flower's record of over 28 years refers to a captive Tuatara at University of Upsala, Sweden, whereas Dawbin (1946) lists longevity at 77 years for one kept by Europeans in New Zealand. This sentence from Dawbin caught my attention, "Dr. Falla (1935) records a specimen which lived in a shell pit at Motiti Island and was said to have been known to the Maoris for 300 years." My final word is that unlike Richard Taylor's report, I have never heard a Tuatara make a croak, much less a squeaking sound. And as far as I know, no guana has ever lived in me, even when I was really sick.

Acknowledgments.—This paper is dedicated to my son James B. Murphy III who is an environmental lawyer for Texas Parks & Wildlife Department in Austin. He has always had an intense interest in protecting biodiversity. He decided to attend law school at Lewis and Clark University in Portland, Oregon rather than becoming a biologist because a number of my herpetological friends and colleagues assured him that greater strides in conservation could be made by adopting this plan, salaries were higher, and lawyers dressed more fashionably, using his father as an example. When he was a student, his law professor invited him to be an observer at the CITES meeting in Thailand. He returned home most disillusioned, complaining about the focus on economic considerations as well as professional and personal agendas, rather than conservation priorities.

I thank Kraig Adler, Lauren Augustine, Judith Block, Don Boyer, Ed Bronikowski, Gordon Burghardt, Jon Campbell, David Chiszar, Claudio Ciofi, Charles Coutris, Kevin de Queiroz, Béla Demeter, Gary Ferguson, Janis Gerrits, Harry Greene, Robert Hansen, Rick Hudson, Ken Kawata, Arnold Kluge, Bill Lamar, Roy McDiarmid, Joe Mendelson, Robert Mendyk, Mandy Murphy, Eric Pianka, Ivan Rehák, David Roberts, Wade Sherbrooke, the late Hobart Smith, Robert Sprackland, David Towns, Gerard Visser, Trooper Walsh, Chris Wemmer, and George Zug for various courtesies.

I am particularly grateful to SI Librarians Polly Lasker and Kristen Bullard, who assisted in locating obscure books and papers and arranging loans for these materials, and Leslie Overstreet and Daria Wingreen-Mason from the SI Joseph F. Cullman 3rd Library of Natural History, who were helpful in locating classic herpetological publications.

GLIMPSES OF THE PAST

Herpetology as a discipline is comparatively modern, but it still boasts its iconic figures and its famous (or infamous) expeditions from the early days. Moreover, reptiles and amphibians often figured in the chronicles of other explorers or adventurers. Today's digital wizardry allows us to enjoy an unprecedented feast of color images featuring rare species from all corners of the globe; but what of the images of yesteryear? Sepia, black & white, and early color-toned photographs are largely unnoticed as they languish in institutional and personal archives. Often, they convey the hardships faced by early explorers and scientists. Some may be humorous; still others show legendary figures at work or at rest. From remote field camps to exotic locales, images from the past stir our imaginations, or they bring back memories of a time when life was different, there was less development, more nature, and more mystery in the world.

In this spirit, *HR* welcomes contributions to this new section. Historical materials should be copyright-free and provided as high-resolution digitized files (consult Section Editor for specifications). Accompanying text should provide relevant context and can include in-text literature citations as needed. Contributions should be submitted to William W. Lamar, Section Editor (e-mail: wlamar@uttyler.edu).

GLIMPSES OF THE PAST

Fred Medem – Crocodile Hunter

Friedrich Johann Graf von Medem, affectionately known to all as "Fred," was a Renaissance man in every sense of the term, descended from nobility, distinguished in wartime, an inveterate traveler, and possessing broad and varied interests and a ravenous curiosity about the world. He had two overriding passions: crocodilians and turtles, and these landed him, at the age of 38, in Colombia in 1950. He plied wild rivers and camped in rainforests in remote sectors of the Magdalena, Orinoco, and Amazon basins as he studied systematics and life histories of Colombia's rich chelonian and crocodilian fauna. Throughout his career he was the leading authority on these reptiles in the neotropics, but he collected everything from mammals to invertebrates and helped countless scientists, always with a smile.

Logistics were formidable and supplies scarce, so it was necessary to spend months at a time in the field. Although it was difficult, Fred was content, as he could quench his thirst for knowledge about all things natural. He never lost his sense of wonder, and on his deathbed was asking questions and expressing excitement about field observations.

ALL PHOTOS FROM MEDEM ARCHIVES, COURTESY OF W. W. LAMAR

"FRED" Friedrich Johann Graf von Medem
29 August 1912 – 01 May 1984.

A juvenile Mottled-face Tamarin, *Saguinus inustus*, perches on Fred Medem's head. Tamarins are often kept as pets by locals and juveniles habitually cling to one's hair for security. El Refugio, Río Guayabero, La Macarena, Meta, Colombia, 1959.

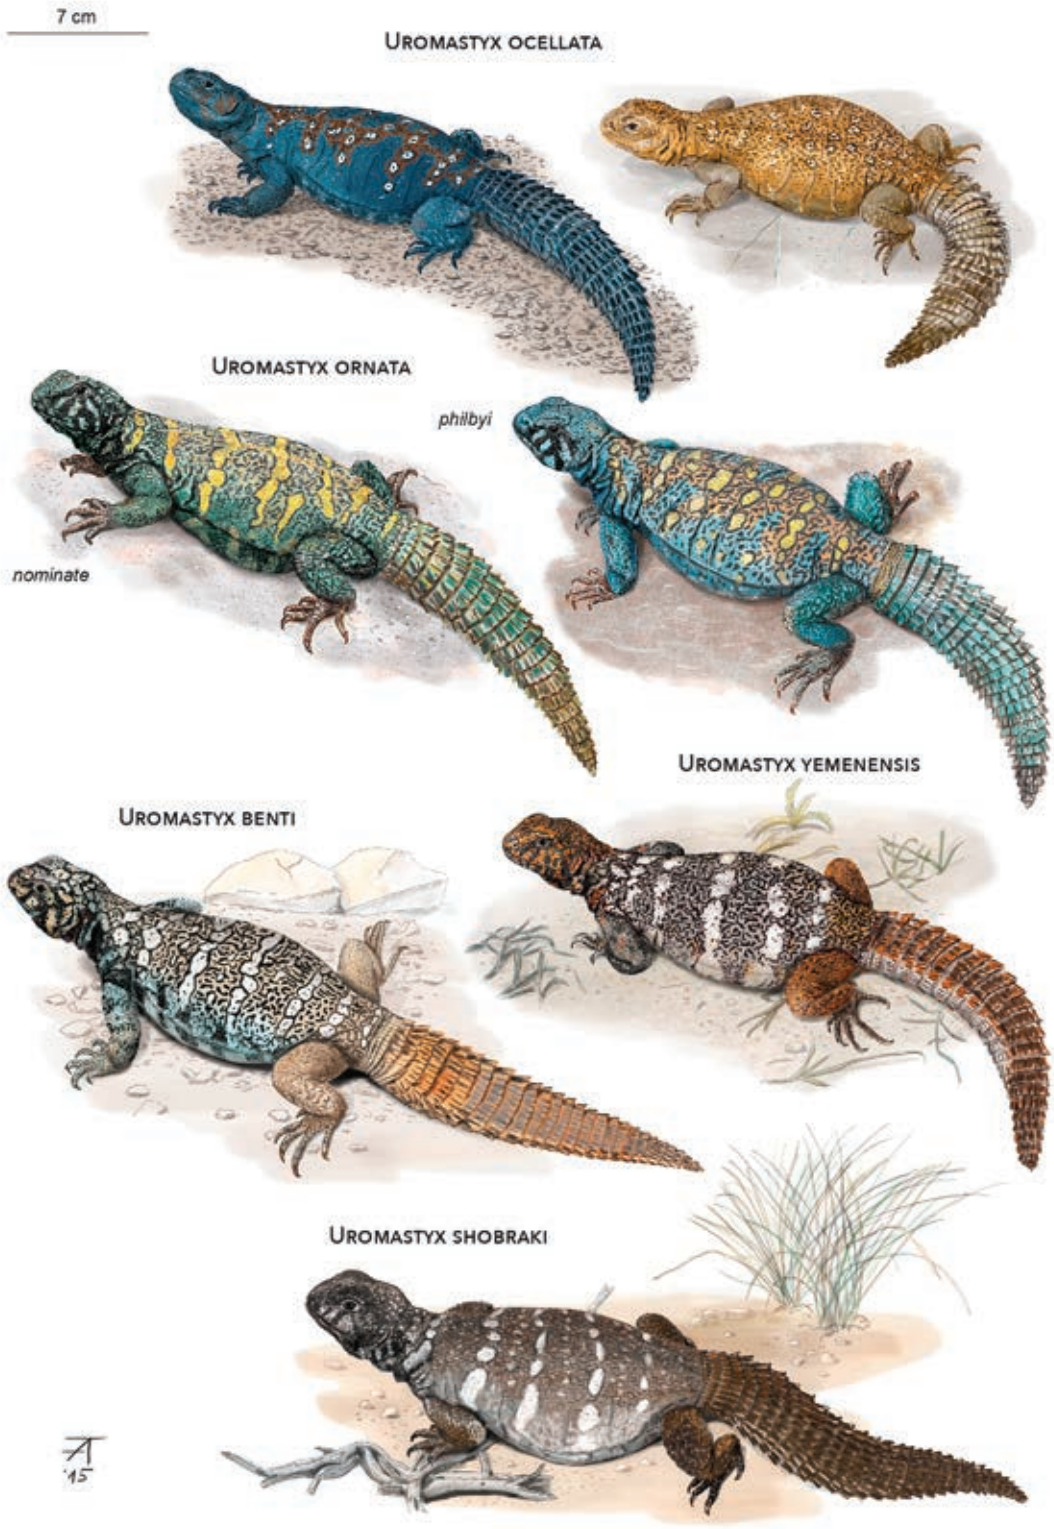
Fred Medem collecting tabanid flies from a male *Caiman crocodilus apaporiensis* which measured 2 meters in length. On his first expedition to the Río Apaporis, Fred was struck by the remoteness and inaccessibility of the upper reaches. What he discovered there was a remarkable narrow-snouted population of caimans which he subsequently described as *Caiman crocodilus apaporiensis*. La Isla, Río Apaporis, Vaupés, Colombia, 21 February 1969.

Fred with a freshly collected female Orinoco Crocodile, *Crocodylus intermedius*, which measured 3.25 m in length. Upper Río Guayabero at El Refugio, La Macarena, Meta, Colombia, 08 March 1959.

The Medem family, cerca 1932. From left to right: Fred's mother Ellen, his father Karl, his sister Else, and a young Fred, ready for adventure.

Fred with a recently captured female Green Anaconda, *Eunectes murinus*, which measured 4.83 m in length and contained 35 embryos. Río Guayabero, La Macarena, Meta, Colombia, 03 February 1959.

Fred and an assistant pose with a Smooth-fronted Caiman, *Paleosuchus trigonatus*. Caño Itílla, Vaupés, Colombia, 13 March 1958.



Carlos Velásquez, longtime aide to Fred Medem, uses a cast net in the early morning. Lack of provisions was a constant problem during lengthy field excursions. Accordingly, fishing and hunting and bartering with locals were of paramount importance. Caño Danta, tributary of the Río Uré, Córdoba, Colombia, 07 February 1963.

Medem with a 3.3-m female *Boa constrictor*. Angostura II, Río Guayabero, La Macarena, Meta, Colombia, 03 January 1957.

Medem feeds a baby Woolly Monkey, *Lagothrix lagotricha*. Fred had an affinity for all animals, and in his later years he kept quite a menagerie at the Instituto Roberto Franco where he was Director. La Isla, Río Apaporis, Vaupés, Colombia, February, 1969.

Western Spiny-tailed Lizards (II): *Uromastyx ocellata* group of species

Arthur Tiutenko – digital painting, 12″ x 16″

Due to the advancement of digital photography in the past two decades, more authors of nature science books, field guides, and articles have opted to use photographs as illustrations they have taken themselves or received from their colleagues. In herpetological books, photographs have become noticebly prominent because amphibians and reptiles can be captured from close distances and with relatively affordable equipment. Very few herpetological publications nowadays are accompanied by drawn or painted illustrations relative to works on other taxonomic groups, such as birds for example. In particular, books covering large systematic groups illustrated with paintings appear rarely in herpetology.

The important role of photography in zoological research is indisputable. In terms of the value of accurate documentation, a photograph may be decidedly superior to a drawing. Nonetheless, even if such factors as aesthetics and classic spirit are left aside, graphical illustrations have practical advantages in science. Painted or drawn organisms, biological events, or other such phenomena can be presented that have not yet been photographed or are potentially impossible to photograph. While a photograph always captures a moment of time and shows a concrete individual subject, more general traits that are common to many or all individuals can be better depicted with a painted or drawn image. Graphical illustrations allow standardized, uniform presentation of subjects throughout the entire publication, whether they are extinct or extant taxa, but whose live photographs do not exist in adequate quality. Further, uniformly high quality illustrated images can be more easily and consistently achieved with paintings and drawings than with photographs obtained from various sources whose quality may vary significantly.

Arthur Tiutenko has taken up the challenge of using the advantages of graphical illustration with one of the most diverse and species-rich lizard families, the Agamidae. Over 90 color plates are estimated to cover all of around 500 currently recognized species. Each plate presents three to eight taxa, depending on maximum physical size of typical individuals. Within a single plate, the animals are depicted with a single scale, in similar postures, and turned into one direction—either left or right. If relevant, polymorphism and sexual dimorphism are also shown. If members of the same genus are spread over several plates, the same scale is used; this should facilitate visual comparison of systematically close taxa. The grouping of taxa on a single plate and the order of plates are based on current phylogenetic relationships. Some distinctive subspecies are shown as well, along with nominate taxa. For instance, a whole plate is dedicated to *Stellagama stellio,* a polytypic species.

Because the taxonomy of this family is frequently reviewed and new taxa are being described, the illustrations will be periodically corrected and updated. One of 12 plates that were completed in 2015 is shown above. This project has a working title called "The Book of Dragons" and is currently projected to continue until 2020, ending with a publication.

All images are drawn and painted freehand and are not based on a single specimen or a single photograph. Several sources always serve as reference for each subject including photographs, preserved specimens, and species descriptions. Arthur uses digital tools to produce his work: a computer, a pen display, and software that simulates traditional art materials and techniques, such as watercolor, gouache, pencils, and ink. Each illustration is first painted as a high resolution image, with maximum detail; subsequently, several such images are merged to create a plate. All illustrations are optimized for book publication: Although each color plate is very large in original (25" × 35", or 63 × 89 cm) and can be printed on a very large paper sheet, optimum look and fine details for close viewing are provided on pages of up to around 12" × 16" (around 30 × 40 cm). Digital images are saved with a resolution of 400 ppi. This makes them suitable for offset printing with 200 lpi, i.e., with highest print quality currently available for books. Printed with a giclée printer on heavy fine art paper, such illustrations look just like paintings on a traditional medium with real brushes and pens. In addition to color plates, Arthur creates maps, diagrams, and drawings that are intended for use as figures in a text for this project.

Arthur Tiutenko is a nature science illustrator and photographer based in Bavaria, Germany. He studied biology and computer science, and is an assistant professor at Friedrich-Alexander University of Erlangen/Nuremberg. Since the 1980s Arthur has participated in a number of herpetological expeditions to Caucasus and Central Asia. He frequently travels on his own in Africa and Asia for zoological collecting and photography, and also leads photography tours and workshops.

Fine art prints of selected art work and photographs by Arthur Tiutenko, including many illustrations from this agamid project, are available in an online shop at Arthur's website: www.nature-images.eu. News and updates on his ongoing illustration projects are published on his Facebook page /*ArthurTiutenkoIllustration.*

ABOUT OUR COVER: *Heosemys depressa*

The Arakan Forest Turtle (*Heosemys depressa*) has had an interesting history since its discovery in the Arakan Hills of Western Myanmar in 1875 (Anderson 1875. Annals and Magazine of Natural History [4]16:282–285; Platt et al. 2003. Hamadryad 27:273–276). Only 33 years after its discovery, the species "went missing," presumed extinct for the next 86 years until in 1994 scientists rediscovered it in a Chinese food market (Platt et al. 2003. Chelonian Conservation and Biology 4:678–682). It was not formally discovered again in the wild until a few individuals were found by researchers in a remote Elephant Sanctuary in 2009 in western Myanmar (Platt et al. 2010. Chelonian Conservation and Biology 9:114–119).

The low density of the known populations, small historical range, and local hunting pressure for Chinese food markets have led to it being recognized as critically endangered (Turtle Conservation Coalition [Rhodin, A. G. J., A. D. Walde, B. D. Horne, P. P. van Dijk, T. Blanck, and R. Hudson (eds.)]. 2011. Turtles in Trouble: The World's 25+ Most Endangered Tortoises and Freshwater Turtles—2011. IUCN/SSC Tortoise and Freshwater Turtle Specialist Group, Turtle Conservation Fund, Turtle Survival Alliance, Turtle Conservancy, Chelonian Research Foundation, Conservation International, Wildlife Conservation Society, and San Diego Zoo Global. Lunenburg, Massachusetts. 54 pp.).

Another major and fortunate discovery came in 2014 when a team led by Caesar Rahman (lead researcher for the Creative Conservation Alliance) discovered a population in the Chittagong Hill Tracts in southeastern Bangladesh, across the border from Myanmar and the Arakan Hills (Rahman et al., *in press.* Chelonan Conservation and Biology). *Heosemys depressa* is considered Critically Endangered on the IUCN Red List and considerable efforts are being made to protect its remaining bamboo habitat in both Bangladesh and Myanmar (Asian Turtle Trade Working Group 2000. *In* The IUCN Red List of Threatened Species 2000 <iucnredlist.org>, accessed 07 October 2015). Several populations also exist in European and American zoos as well as various private collections, of which some have been successful in captive breeding.

Four species are currently placed in the genus *Heosemys* (Turtle Taxonomy Working Group (IUCN/SSC Tortoise and Freshwater Turtle Specialist Group [van Dijk, P. P., J. B. Iverson, A. G. J. Rhodin, H. B. Shaffer,and R. Bour]. 2014. Turtles of the World, 7th Edition: Annotated Checklist of Taxonomy, Synonymy, Distribution with Maps, and Conservation Status. Chelonian Research Monographs No. 5, Chelonian Research Foundation. doi:10.3854/crm.5.000.checklist.v7.2014). Collectively, these species occur in Southeast Asia, including the Philippines.

Our cover image was recorded by **Scott Trageser** in Bandarban, Bangladesh. Scott's equipment consisted of a Nikon D810 with a Nikkor 16mm f/2.8 Fisheye lens (f/6.3, 1/250 sec, ISO 400). Lighting was accomplished by two SB700 strobes with softboxes positioned off camera. Scott is a self-described "nature junkie" and photographer (NatureStills Photography / www.naturestills.com). An avid traveler and conservation biologist, Scott travels the world working with various NGOs and research groups to document and conserve dwindling biodiversity.

SSAR BUSINESS

2015 Annual Meeting at University of Kansas, Lawrence, Kansas

The 58th Annual Meeting of SSAR took place from July 30th to August 2nd, 2015 on the beautiful University of Kansas campus in Lawrence, Kansas (Figs. 1, 2). This meeting was the first in ten years since SSAR last met on a university campus (excluding the World Congress in Vancouver). Plans for this meeting began around five years ago, followed shortly thereafter by an informal offer from Rafe Brown to host the meeting at the University of Kansas (KU). KU is a particularly appropriate venue, as an institution with a distinguished history of herpetological research and education, to which many of today's herpetologists can trace their roots, and having hosted previous SSAR meetings in 1977 and 1996 (Fig. 3). The 2015 meeting sprung from a desire, shared by many members of SSAR, to occasionally hold a meeting reminiscent of the smaller, more intimate gatherings that older members recall. The primary aims were to hold an especially student-friendly meeting, honor some of our distinguished senior herpetologists, and bring back some of the special features of SSAR meetings that had been lost over the years. The Board regards it as important for student members, at least once during their student years, to experience a style of meeting different from the successful JMIH events that we have become used to in recent years.

The 2015 meeting was a resounding success, certainly on a par with the great SSAR meetings of the past, due largely to years of planning and hard work as well as a commitment to the future of the Society. SSAR met in association with Partners in Amphibian and Reptile Conservation (PARC), Center for North American Herpetology, Kansas Herpetological Society, Missouri Herpetological Society, Arkansas Herpetological Society, and the International Society for the History and Bibliography of Herpetology. The local hosts were Rafe Brown (co-Chair), Bill Duellman, Rich Glor (co-Chair), George Pisani, and Linda Trueb. Kraig Adler was SSAR's official liaison for the meeting. Student co-liaisons were Karen Olson, Tashitso Anamza, and Jesse Grismer. Stacey Walters, Kevin Curry, Justine Hamilton, Sharon Leatherman, Jeremy Whetstone, and Jennifer Schmitendorf also worked hard to keep

things running smoothly. Kudos to the whole team for some last-minute adjustments, and especially to Rafe and Rich, who somehow managed to turn a problem with mold into free drinks at multiple events!

Approximately 452 herpetologists attended the meeting. This included 161 regular students, 18 student recipients of the Carl Gans Registration Awards, 13 graduate student volunteers, six Distinguished Seniors, five exhibitors, 165 regular registered members, 23 non-members, and 22 other miscellaneous registrants.

SSAR was pleased to have in attendance three pre-baccalaureate students—Ali Metler, Justin Lee, and Eli Haines-Eitzen. The first two have previously attended our annual meetings and Justin and Eli were sponsored by SSAR this year. Justin was the first recipient of the SSAR pre-baccalaureate award, at the 2010 JMIH meeting in Rhode Island. Justin and Eli participated in the mentor program (along with seven other mentees), ably organized by Kris Kaiser, Andrew Durso, and Joe Mendelson, III.

One of the many enjoyable aspects of the meeting was its "manageable" size, in terms of numbers of attendees, number of concurrent sessions, and proximity of events. It was easy to interact with everybody! Over the three days of presentations, there were four plenary sessions, 27 oral sessions (with 155 presentations), 70 poster presentations (Figs. 4–5), and five symposia. SSAR sponsored two symposia: "Frontiers in Integrative Organismal Biology" and "Bones, Frogs, and Evolution" (Figs. 6–7) Thanks to Rafe Brown and Rich Glor for organizing the former. Dave Blackburn, Rafe Brown, Dave Cannatella, and Anne Maglia organized the latter, held in honor of Linda Trueb. PARC sponsored three symposia: "Identifying Priority Areas for Herpetofauna Conservation," "PARC's Partners Focusing on Habitat," and "Communicating Herpetofaunal Conservation to the Public."

Social and Professional Events

The meeting kicked off on July 30th with a full-day Board meeting and several tours. These included the KU Natural History Museum, where Rich Glor provided a behind-the-scenes look at the research collections (Fig. 8). George Pisani led many tours

to the Henry Fitch Natural History Reservation (Fig. 9). This was such a popular event that additional tours were added. A Live Animal Exhibit of 100 Kansas herp species, complete with photographic stages, was assembled by the Kansas Herpetological Society. For bibliophiles, a popular destination was the Classical and Illustrated Herp Books Exhibit at KU's Spencer Library. This was followed in the evening by the always-anticipated Presidential Travelogue. President Bauer introduced this year's speaker, Miguel Vences (Technical University of Braunschweig), noting that one of the pleasures of being President was being able to select the Travelogue speaker. The title of Miguel's presentation was "Inventory of an Imperiled Paradise: Two Decades of Herpetology in Madagascar." Miguel has been active in herpetological conservation on a global scale and is sometimes referred to as "Mr. Madagascar." He referred to Madagascar as a "micro-continent" with habitats ranging from rainforest in the East to dry regions in the Southwest. Madagascar, a highly modified, biodiversity conservation hotspot, is home to around 300 described species of frogs, around 400 described species of reptiles, and many species yet to be described. Within a single location one can find up to 110 species of frogs and many species are "micro-endemic" with very small ranges. The early days of Miguel's research in Madagascar (early- to mid-1990s) were made challenging by poor infrastructure and a lack of funding. Later expeditions were larger and better equipped, such that travel to more

remote sites was possible. As most Malagasy frog species cannot be identified reliably based solely on morphology, the advent of DNA barcoding in the mid-2000s led to an "explosion" of species numbers. A 2014 estimate placed the number of species at 500–600. Miguel referred to taxonomic species descriptions as the "new bottleneck." He cited deforestation, habitat destruction, and climate change as threats to species on Madagascar.

For many, the highlights of the meeting were the multiple plenary sessions, three sponsored by SSAR, and one by PARC. On the morning of July 31st, the first plenary session began with a welcome and introductory comments by local co-Chairs Rafe Brown and Rich Glor. Rafe referenced the 100-year history of herpetology research at KU and indicated that much of that history was represented "in the flesh" at this meeting. He particularly welcomed relatives of Edward H. Taylor and Henry Fitch in the audience. Leonard Krishtalka, Director of the Biodiversity Institute at KU, echoed Rafe's welcome. Following a slight wait for an appearance by the Mayor of Lawrence, during which Rich Glor began to recount a story of meeting with the Mayor and an uncomfortable allusion to snakes in city hall, the Mayor, Jeremy Farmer, arrived (Fig. 10). The Mayor then proceeded to finish Rich's story. Despite being bitten by a copperhead at age seven, the Mayor had declared this "International Amphibian and Reptile Week" in Lawrence and presented the society with a proclamation that acknowledged reptiles and amphibians as an essential part of the ecology of Kansas and the importance of the University of Kansas Biodiversity Institute as home to the fifth largest collection of reptiles and amphibians in the USA with more than 340,000 specimens representing more than 5000 species from 156 countries.

Rich then acknowledged the many local student volunteers who dedicated many hours to make the 2015 meeting a reality (Fig. 11). Jesse Grismer and Karen Olson drew attention to the many student-centered activities offered over the next few days, including the Herp Quiz, the PARC lunch, the SSAR Student Social, the Picnic, and even a (non-SSAR related) Tractor Pull Competition in town!

Rafe Brown spoke for a few minutes more about KU taking its herpetological history seriously and being aware of its importance. He mentioned that the program traces its history back to the early publications of Edward H. Taylor based on his work in the Philippines in the 1910s. He then acknowledged Ed's grandson, Dr. Philip Taylor, and his family, as well as Alice Fitch Echelle, Henry Fitch's daughter, and her family, in the audience.

A number of individuals representing participating societies then spoke. Dan Fogell introduced officers of the Kansas Herpetological Society, followed by J. J. Apodaca who introduced PARC officers. Suzanne Collins and Kelly Erwin represented the Center for North American Herpetology and presented the Slowinski Award *in absentia* to Paola Carrasco. SSAR Past-President Bob Aldridge introduced officers of the Missouri Herpetological Society and Glen Manning represented the Arkansas Herpetological Society. Richard Wahlgren represented the International Society for the History and Bibliography of Herpetology and noted that this society was founded in 1996 at KU's Spencer Library.

Dora Pinou, representing the Herpetological Education Committee, presented the Meritorious Teaching Award in Herpetology to Brad Shaffer (University of California at Los Angeles) commenting on the fact that, over his career, Brad has mentored 19 graduate students and 16 post-docs.

Kraig Adler was asked by Rafe Brown to recount some of the history of SSAR, including its origination as The Ohio

Herpetological Society (OHS) founded by a handful of teenagers (including Kraig) in 1958. Kraig pointed out Steve Tilley and David Dennis in the audience as other founding members of OHS (Fig. 12). From humble beginnings, SSAR has grown to become the largest professional herpetological society in the world.

Jen Williams and Priya Nanjappa spoke of the mission of PARC to "conserve amphibians, reptiles and their habitats as integral parts of our ecosystem and culture through proactive and coordinated public-private partnership" and mentioned some relevant guidelines and handbooks that are available from PARC. Priya then presented the Alison Haskell Award for Excellence in Herpetofaunal Conservation to John Jensen (Georgia Department of Natural Resources). Kurt Buhlmann (Savannah River Ecology Laboratory, University of Georgia), the PARC Visionary Leader Award recipient for 2015, spoke about where we might focus our efforts to secure viable populations and prevent loss of herp species in the next decade.

Following a break, President Bauer briefly introduced SSAR officers and then gave the SSAR Presidential Address, including a special message for students. Aaron began with a question—"Why is this meeting different?" For most people under age 40 at the KU meeting, their only experience with a herp meeting is that of JMIH. Aaron acknowledged that those meetings work well, but they are a very different type of meeting than we are aiming for in 2015. Because of the large number of attendees, including ichthyologists, at the combined meetings, these are held in convention centers and large hotels and are organized by meeting professionals rather than local herpetologists. Because of this, some of the "special touches" of previous SSAR meetings have been lost, e.g., live animal exhibits, the herp quiz, the AV shows, etc. Those signature events are being brought back to this meeting and SSAR is proud of its long tradition of being student-centered and of being able to offer students more than just our journals. Aaron introduced the Distinguished Senior Herpetologists attending the KU meeting (Vic Hutchison, Bayard Brattstrom, Alan Leviton, William Duellman, Itzchak Gilboa, and David Wake) and encouraged students to attend the reception in honor of these individuals. He referred to them as "pillars in our field," and pointed out that the reception was a rare opportunity for students to mingle with individuals who, sadly to many, are just renowned names in books or on papers. Aaron then moved to the other end of the age-spectrum and welcomed Justin Lee and Eli Haines-Eitzen, the two pre-baccalaureate students sponsored by SSAR. Aaron acknowledged the very generous gift from the Carl Gans Charitable Trust to SSAR that will support student attendance indefinitely at our meetings. In return for this support and the many other things that SSAR is pleased to provide to student members, Aaron encouraged them to get involved in the society. He referred to SSAR as "a very special society for students."

Aaron then presented the handsomely framed original artwork, featuring an Eastern Collared Lizard by David Dennis, that was featured so prominently on the giveaway meeting poster (Fig. 13) to the Herpetology Division at KU as SSAR's tribute to everyone in the Division who helped with meeting organization. He returned to his special message to students and noted that one of the things we (and all other organismal-based societies) worry about is decreased membership. He acknowledged that there are a variety of reasons why this is happening. When we lose members, we lose the most important part of our revenue stream. No revenue means no journals, no books, no meetings, no travel awards, no research awards, etc. We are a non-profit organization and none of our officers (President, Secretary, Treasurer, Members of the Board), Editors, or Committee chairs receive any compensation—we are all volunteers. As a society we value this culture of service. Aaron recalled his days as a graduate student when his Ph.D. advisor Marvalee Wake made it very clear to him that he was expected to go to professional meetings and eventually assume duties within societies. (To all who know Aaron, it is obvious that he is continuing that tradition with his own students.) Aaron said that this is the 26th SSAR meeting that he has attended (he admitted to missing a few when he was in the field as a student, but even then felt guilty about not being present!) and he encouraged students to invest in this society and become active members. He said he hopes they have such a good time at this meeting that, if they don't already have the mindset that "to be a herpetologist is to participate," it will develop. Aaron encouraged students and all SSAR members to attend the Business Meeting to find out what is happening in the society. He said they might find it tedious (actually, it was not!), but at least they didn't have to attend the day-long Board Meeting!!

Aaron ended on a somber note and reminded us that the work of herpetologists today is built on the foundations established by those who have come before. He then gave a moving tribute to, what he acknowledged, was only a partial list of herpetologists who had passed away since our 2014 meeting: Ray Semlitsch, Doug Rossman, Dick Peterson, Charlie Painter,

FIG. 15. Harry Greene presents SSAR Plenary Lecture about Henry Fitch's life.

Eduardo Bustos-Obregon, James Dixon, Herndon Dowling, Jack Fouquette, James Organ, Victor Quesnel, Graham Turbott, and Margarita Metallinou.

In anticipation of the 8th World Congress of Herpetology (WCH) in Hangzhou, China, Dr. Xiang Ji (WCH Secretary General-Elect and Local Host) gave a promotional presentation. He mentioned the long history of herpetological research in China dating back 2000 years and the increasingly rapid growth of research in this area. Tours will be organized before and after the meeting (which will run August 15–21, 2016) and the deadline to submit abstracts is June 15, 2016. Website: www.worldcongressofherpetology.org/ and local contact: wch2016@vip.163.com

David Hillis (University of Texas at Austin) then gave the first plenary lecture of the meeting: "Progress in Reconstructing the Phylogeny of Amphibians and Reptiles: Where We've Been and Where We Need to Go" (Fig. 14). Dave noted that towards the end of the 1970s, when there was much discussion about the principles of cladistics, we were limited by the abilities of our computers. By the late 1970s there were so few papers that included phylogenies that you could easily read them all. He recalled setting up a molecular biology lab from scratch at KU as he was working towards his dissertation entitled "Phylogeny and Biogeography of New World *Rana*." In 1985 at the SSAR meeting in Tampa he began talking with Craig Moritz about a book on molecular systematics. That book (*Molecular Systematics*, Hillis and Moritz) appeared in 1990 just as molecular biology was about to "take off." In the 1970s and 1980s it was a matter of needing more data, in the 1990s and 2000s we needed better sampling on taxa, by 2010 we were finally getting good data sets, but questions were being asked about whether the models we were using were up to the task of analyzing the data. Dave posed the question—"Are we overconfident in the conclusions we draw from the models we use?" Errors in these models fall into two categories: easy to fix sampling errors, and more difficult to fix, and often ignored, errors in assumptions.

The Plenary speaker on Day 2 was Harry Greene (Cornell University) who spoke on "Life and Times of a KU Herpetological Icon: Henry Fitch and 70 Years of Snake Ecology" (Fig. 15). By almost any measure Henry Fitch (1909–2009) was a remarkable herpetologist—he collected thousands of specimens for museums and he published over 4000 pages in 200 papers. But what interests Harry is "Why did he do it?" In trying to answer this question for us, Harry recounted some of the details of Henry's life. He entered the University of Oregon in 1926 at around 16

PHOTO BY R. W. HANSEN

FIG. 16. Tyrone Hayes presents the PARC Plenary Lecture about the impact of pesticides on natural ecosystems.

years of age, he arrived at the Museum of Vertebrate Zoology at University of California at Berkeley in 1931, completing a Masters thesis on the natural history of *Elgaria* in 1933 and a Ph.D. thesis on the systematics of *Thamnophis* in 1939. In 1948 he was hired by KU as an ecology instructor and superintendent of the new Natural History Reservation. Over time he gained the nickname "the father of snake ecology." At one point a KU graduate student asked "How many copperheads does he need to mark?" In 1980 at the age of 71, he "retired." However, as Harry noted, Henry just kept going. In an attempt to figure out what made Henry "tick" and how he knew what to measure, Harry got nowhere with direct questions to Henry, so his questions became more oblique. Harry concluded that Henry was driven by innate curiosity, not theory (although he was not naive to theory). As Henry said "I've always spent time on whatever interested me most—with or without grants—and have greatly enjoyed all my projects, especially the fieldwork . . . I wouldn't change a thing. People who work with animals in the field, whether snakes or birds or rodents or monkeys, find it deeply satisfying and wouldn't trade it for any other career—even though it may not be financially rewarding."

Tyrone Hayes (University of California at Berkeley) was the PARC Plenary speaker on the third day of the meeting (Fig. 16). His talk was titled "From Silent Spring to Silent Night: A Tale of Toads and Men." As Tyrone often does, he began his talk with acknowledgments, thanking those who have influenced his life and career. He recalled advice from his grandmother—"Don't preach, don't teach, just tell a story!"—and that's what he proceeded to do. He spoke of being contacted early in his academic career by Novartis to study the effects of the herbicide atrazine on *Xenopus* frogs. In the late 1950s, despite being banned (or in "Novartis-speak" "denied regulatory approval") in Europe, atrazine was still in use in the USA. Tyrone's research showed, among other effects, that atrazine inhibited the growth of the larynx in male frogs and that the male gonads were "not normal." Further work revealed hermaphroditism caused by exposure to atrazine, and Tyrone became interested in the questions of whether these individuals are females with testes or males with ovaries, and what happens when they become adults. He carried out behavioral trials comparing control and atrazine-treated males and found that the controls had higher levels of testosterone, greater mating success, and higher fertilization rates than seen in the experimental group. He referred to these effects in a paper in PNAS as "chemical castration" (a term he said, not surprisingly, Novartis hates). He then turned his attention to the effects of atrazine in the wild, given that he found sufficient atrazine in water, even drinking water, to cause the above effects. Tyrone said that many people don't care about frogs the way we do; however, in many respects they are the new "canary in the coal mine," in the same way as the birds that Rachel Carson referred to in her book, *Silent Spring*. He reported that effects of atrazine, similar to those he saw in *Xenopus*, have now been seen in fish, reptiles, birds, and mammals. Those mammals include humans. Tyrone cited a recent study showing increased atrazine levels in men with fertility problems and indicated that some effects are also seen in women. His interest in aquatic frogs has taught him about another aquatic organism—embryonic humans. Both are exposed to environmental chemicals. He mentioned the existence of second-generation effects, i.e., evidence of exposure showing up in the grand-offspring of those exposed. Tyrone finished by referring to chemical exposure more broadly as an issue of environmental justice. He referenced his home state of California with the 5th largest economy in the world and one in nine jobs in agriculture. California uses more pesticides than any other state in the USA and 90% of field workers (exposed to these chemicals) are Hispanic, thus the "consequences of atrazine exposure are more likely to be felt by people of color."

In terms of special events throughout the meeting, we welcomed back some old SSAR favorites. For example, the live animal exhibit, run by members of the Kansas Herpetological Society, was held throughout the meeting and featured all 100 species of amphibians and reptiles found in Kansas (except for the venomous ones, which had to be excluded due to local statute). And, for those confident enough to put their herp know-how to the test, the Herp Quiz was offered on two days.

A special reception was held on Saturday, August 1st, for several authors to sign copies of their books. Bill Duellman signed copies of his new books just issued this summer: *Herpetology at Kansas: A Centennial History*, and *Marsupial Frogs:* Gastrotheca *and Allied Genera* (Fig. 17). Copies of the first title were presented to every meeting registrant. As a special addition, Philip Taylor and Alice Fitch Echelle, grandson and daughter of the two KU herpetology icons featured in Bill's book, were also on hand to sign the chapters about Ed Taylor and Henry Fitch, respectively (Figs. 18–19). Sally Haines, author of the book, *Slithy Toves: Illustrated Classic Herpetological Books at the University of Kansas* (SSAR 2000), signed complimentary copies of her book.

Throughout the meeting, a special display of herpetological books was exhibited at the Kenneth Spencer Research Library.

KU possesses one of the world's greatest collections of books on amphibians and reptiles. We are grateful to several persons for arranging an exhibit illustrating the history of herpetological book illustration over the past five centuries (Karen Cook, Elspeth Healey, Whitney Baker, Roberta Woodrick, Caitlin Donnelly, Beth Whitaker, and Sally Haines, plus three student trainees, Ryan Ridder, Megan Sims, and Sydney Goldstein). This exhibit was also tied into the satellite meeting of the International Society for the History and Bibliography of Herpetology, which met at Spencer Library on Monday, August 3rd.

In 2013, in anticipation of the KU meeting, the SSAR Board allocated funding to update and digitize the audio-visual shows that David Dennis, Eric Juterbock, and Kraig Adler produced in the early 1980s for use at SSAR, SSAR/HL, World Congress, and other meetings in the USA, Canada, and the UK. The shows celebrated the field of herpetology, the people, the animals, and the places they live. These old shows not been shown in at least a decade because the technology was out of date (six slide projectors coordinated by an ancient computer) and they were not of high quality.

Kraig Adler introduced the updated versions of two of the original four shows ("Amphibians of the Appalachians" and "Herpetologists Past and Present" (plus an alternate version of "Amphibians of the Appalachians" with species and localities identified) when they premiered in the evening of July 31st (they were shown again on August 2nd). Getting to this point was truly remarkable. Over a five-year period, to update "Amphibians of the Appalachians" David and Eric made around 20 trips covering all seasons to the original locations. All of the digital photographs taken were natural (i.e., no nature faking!). "Herpetologists Past and Present" was also updated and provided a quick chronology of the field. It also would have benefitted from having another version with the photographs from the younger days of some of the present-day herpetologists identified!

On the evening of July 31st, just prior to the AV shows noted above, there was a special reception honoring the Distinguished Senior Herpetologists to which all meeting attendees were invited (Figs. 20–23). On the same evening, a special banquet was held in the Panorama room of the Museum of Natural History for all KU herpetology graduates, sponsored by Bill Duellman and Linda Trueb (Fig. 24).

Two afternoon workshops followed the PARC symposium on "Communicating Herpetofaunal Conservation to the Public" on August 2nd. "Distilling your Message" was run by Christine O'Connell from the Alan Alda Center for Communicating Science at Stony Brook University in New York. Participants worked on "perfecting" their three-minute elevator talks about their science (Fig. 25).

The annual SSAR student reception was, as usual, well attended. Invited professionals, including many of the senior herpetologists, mingled with graduate and pre-baccalaureate students (Figs. 26–27). It was quite an age range! The live auction was adjacent to the reception and followed immediately. Food and drinks were readily available throughout the evening. Auctioneers Greg Watkins-Colwell, John Moriarty, Frank Burbrink, Rich Glor, David Hillis, and Joe Mendelson, III did a masterful job of keeping the evening fun and profitable for SSAR, raising over $8,000 for student activities. Students assisting the live auction were Krista Mougey (Texas Tech University), Megan Smith (University of Mississippi), Catriona Hendry (George Washington University), John Phillips (University of Oklahoma), Elyse Freitas (University of Oklahoma), Kai Wang (University

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
58th Annual Meeting

RECEPTION TO HONOR DISTINGUISHED
SENIOR HERPETOLOGISTS

All Registrants Are Invited

UNIVERSITY OF KANSAS
THE COMMONS (ground floor of Spooner Hall*)
FRIDAY, JULY 31, 2015 • 6:00 TO 7:30 PM

THIS FRIDAY (JULY 31st) SSAR IS PRIVILEGED TO HONOR A GROUP OF SENIOR colleagues who have been major figures in herpetology for over half a century. Their biographies and portraits are provided in this document. Please join us in recognizing their long and distinguished careers and their many significant contributions to our field. This event is open to all registrants without charge. There is a small room connected to The Commons, opposite the front door and on the east side of the building, where some of our distinguished seniors may wish to greet visitors in relative quiet.

During two previous meetings held at the University of Kansas, SSAR has recognized outstanding senior herpetologists. In 1977, we honored Edward H. Taylor and in 1998 three others—Roger Conant, Henry S. Fitch, and Hobart M. Smith. Those students who were able to meet these giants of herpetology, all now deceased, will long remember their conversations with them.

All meeting participants are invited to join us to recognize this year's honorees and to meet those persons who have confirmed their attendance or otherwise indicated that they plan to attend this week's meeting in Lawrence. We especially encourage our students to take this unique opportunity to meet these luminaries in our field. Also joining us as special guests at Friday's reception are Philip Taylor, Edward Taylor's grandson and an amateur herpetologist, and his family, as well as Alice Fitch Echelle, Henry Fitch's daughter and occasional field collaborator, and her family. Further information about them is provided at the end of this brochure.

* Historic Spooner Hall is located along Jayhawk Boulevard, directly across the street from Dyche Hall (the Biodiversity Institute and Museum of Natural History).

FIG. 20. Brochure for the SSAR reception honoring several distinguished senior herpetologists: Bayard Brattstrom, Bill Duellman, Itzchak Gilboa, Vic Hutchison, Al Leviton, and David Wake. The brochure had bios and portraits of the honorees.

FIG. 23. Vic Hutchison talking with students at the seniors reception. The first Victor Hutchison Best Student Poster Awards were presented at the KU meeting.

Vinny Farallo (co-Chair Student Travel Awards Committee) oversaw the silent auction again. Recipients of the $500 SSAR Student Travel Awards took turns to work the silent auction table for 2–3 hrs throughout the course of the meetings. The Silent Auction raised just over $1,000 for student activities.

The winners of the Herp Quiz were announced by Jesse Grismer during the live auction. They were Joseph Chase, Mike Gründler, Eli Haines-Eitzen, Justin Lee, and Erik Wild. They each received a cash prize, and, later, a beautiful glass etching produced by the multi-talented Ronn Altig (Fig. 32). Many will recall the wine glasses that Ronn fashioned for the banquet at our 50th anniversary meeting in 2007. The meeting wrapped up on the evening of August 2nd, with a picnic held on the roof of the seven-story-tall Oread Hotel on the KU campus, the highest point in the entire county (Figs. 33–36).

Board and Business Meeting Summaries

SSAR Board Meeting

Society President Aaron Bauer called the Board Meeting to order at 0902 h on July 30th, 2015 in the Kansas Union, University of Kansas, Lawrence, Kansas. In attendance were the following members of the Board of Directors, Editors, and Committee

Chairs: Kraig Adler (Editor, *Contributions to Herpetology*, and chair, Long-Range Planning Committee), Bob Aldridge (Past-President), Robin Andrews (Board Member, Reg. 2018), Paul Bartelt (co-Editor *Journal of Herpetology*), Breck Bartholomew (Publications Secretary), Aaron Bauer (President; Editor, *Facsimile Reprints in Herpetology*), Rafe Brown (Chair, Seibert Award Committee; Local Meeting co-Chair, 2015), Alison Cree (Board Member, non-US 2016), Raul Diaz (Member, Website Subcommittee), Tiffany Doan (co-Editor *Journal of Herpetology*), Richard Durtsche (Coordinator, Symposium Committee), Vincent Farallo (co-chair, Student Travel Award Committee; Member, Website Subcommittee), Rich Glor (Local Meeting co-Chair, 2015), Robert Hansen (Editor, *Herpetological Review*), Lisa Hazard (Board Member, Reg. 2016), Michelle Koo (Member, Website Subcommittee), Kim Lovich (Board Member, Conserv. 2018), John Moriarty (Editor, *Herpetological Circulars*), Joe Mitchell (Editor, *Herpetological Conservation*), Ann Paterson (Treasurer), George Pisani (Trustee), Marion Preest (Secretary), Al Savitzky (SSAR Representative to AIBS and BioOne), Rick Shine (President-Elect), Lynnette Sievert (Chair, Kennedy Student Award Committee), Carol Spencer (Chair, Website Subcommittee), and Greg Watkins-Colwell (Board Member, Reg, 2016; Organizer, SSAR/HL Live Auction). Additional society members present included David Auth, Vic Hutchison, Roy McDiarmid, Dave McLeod, and Joe Mendelson III.

Introductions were made and minutes of the 2014 Board of Directors Meeting (Chattanooga, Tennessee) were approved. President Aaron Bauer then called for a round of applause for Local Meeting Committee co-Chairs, Rafe Brown and Rich Glor, in appreciation of their hard work and finally reaching the opening day of the 2015 KU meeting.

Officers' Reports

President Bauer reported that the Board approved funding of half (~ $2,000) of the Alan Alda Workshop for the KU meeting. PARC will cover the remaining half. Sixteen slots will be available at the workshop, half of which will be for SSAR members. In November 2014, President Bauer signed a joint letter to Director Ashe (US Fish and Wildlife Service) requesting urgent action to prevent introduction of *Batrachochytrium salamandrivorans*, which poses a severe threat to native amphibians in the USA and neighboring countries.

In July 2015, President Bauer welcomed the arrival of the new SSAR website and thanked the committee (Raul Diaz, Vincent Farallo, Michelle Koo, and Carol Spencer) for their outstanding work. He made the following appointments:

- Greg Watkins-Colwell, to chair the SSAR Membership Committee;
- Jeremy Feinberg, to chair the Student Participation Committee.

In December, Aaron wrote to Vic Hutchison to announce that the Board unanimously and enthusiastically voted to change the name of the "SSAR Student Poster Awards" to the "Victor Hutchison Student Poster Awards." (Vic served as SSAR President in 1999.)

Treasurer Ann Paterson reported that SSAR had a mixed financial year in 2014. Most expenses were close to predictions and our investments did well. However, membership income is a bit lower this year and publication income has decreased again. She reported that we have made some substantial changes to our accounting procedures and investment management this year. While this means that some numbers are estimates, she hopes that these changes will simplify reporting in the future. We underspent our budget this year by $53,946. This was largely a result of lower expenses because income was also down.

Ann noted that we have transitioned to a new accountant, Beverly Powell. We have moved our investments from Fidelity Investments to the Truman Heartland Community Foundation (TCFH). This means that our investments are now being managed by experienced investment managers. Additionally, it now requires a more complex process to withdraw funds (increasing security). This change allowed us to set up investment accounts that match our specific Restricted and Non-Restricted funds, meaning that we can invest each one using the most appropriate strategy. It also affects the way that money will be moved out of the funds when awards or other withdrawals are made. This transfer brought our book and market value to be the same at the point of transfer. Most nonprofits currently record and report their investments at market value and this is the protocol used by THCF. Currently, these values are very close for our funds.

Ann also reported that our relationship with the Truman Heartland Community Foundation allows contributions to be made on the foundation website, www.thcf.org, for any funds housed there. Individuals can make a one-time donation or set up a recurring donation on a monthly, quarterly, or annual basis. SSAR now has an Amazon "Smile" account and it is possible to make small donations to the Society when shopping on Amazon.

The Treasurer now receives membership reports, deposit reports, and profit-and-loss statements monthly from the Publications Secretary's office. Ann hopes this will improve the accounting system. Although SSAR adopted a new credit card processing

system in 2015, Ann suggested we need to consider whether to stop accepting credit cards at auctions or adopting a newer, more expensive system. She also suggested that we need to consider ways to increase oversight of SSAR finances.

Ann plans to overhaul the way that SSAR finances are reported next year. She says that this will allow her to more rapidly generate information as needed, as well as more accurately reflecting SSAR's current expenses and income categories.

Secretary Marion Preest provided Officers, Editors, and Committee Chairs with minutes of the 2014 Board Meeting, summarized the 2014 Annual Meeting for publication in *Herpetological Review*, and regularly updated the SSAR letterhead to reflect changes in personnel. She informed the Editors of *Journal of Herpetology* and *Herpetological Review* of these changes and provided various updates for Vinny Farallo (webmaster). Marion also wrote letters to student winners of various awards and prepared announcements for publication in *Herpetological Review*. She compiled the 2015 Annual Report, prepared agendas for the Board and Business meetings for the 2015 Annual Meeting, and was again involved in organizing a reception for student members of SSAR to be held at the Annual Meeting. Marion called for votes from the Board on various issues, e.g., SSAR Presidential Awards, symposium proposals, etc. She circulated documents that needed to be signed by members of the Board, e.g., Conflict of Interest, and dealt with many emails and phone calls from SSAR members and the general public.

Breck Bartholomew (Publications Secretary) reported that he submitted his resignation as Publications Secretary earlier in 2015. He has given SSAR through 2016 to find a replacement or to decide what to do with the publications. He will also be closing ZenScientist.com by September 30, 2016. This gives the society plenty of time to fill the multiple duties he has been performing. Breck informed the Board that, in his view, our publications series have become a liability and in their present form are no longer viable for the society. With the amount of information available on the internet, most people feel printed literature is burdensome and difficult to work with. Few people are buying books, and in many cases they simply do not want books, even if they are given to them. People do seem to have an increased desire for pdfs of books. For people who are not at institutions, there are many websites, forums, groups, etc., where people can obtain most books and journal articles for free. Unless donations, authors, or advertisements are paying for books to be published, there seems little possibility for hard-copy publishing to remain a viable option for the society. Breck recommends that we consider discontinuing some series and limiting the print runs of books that are published. Perhaps a print-on-demand type printing should be considered. The quality of print-on-demand tends to be poor, but perhaps there are higher quality options available.

According to Breck, another option might be for the society to start publishing books of general interest with the goal of distributing these through large distributors. This type of series might also help recruit members. Large publishers regularly publish books on amphibians and reptiles for the general public.

Breck's goal over the remainder of his term as Publications Secretary is to liquidate as many books as possible. After the KU meeting he will contact remainder dealers to try to sell off several titles. SSAR does have several books that remainder dealers are not interested in.

In addition to books, Breck has the overruns of *Journal of Herpetology* and *Herpetological Review*. He has been reducing the numbers held to ten copies once the journal issue is two years old. Most of the overrun copies are mailed to late subscribers or to replace lost or damaged copies.

Breck suggests SSAR consider having Allen Press handle back issues of the journals, as they used to do. There are fees associated with this service. Allen Press will charge a storage fee, a fee for each journal sent, and even to destroy older journals. Allen Press will need very specific instructions in terms of what to dispose of. This will help reduce storage costs.

Page charges are currently the responsibility of the Publications Secretary's office. The Publications Office has been assisting *Herpetological Review* by billing for advertisements and mailing out pdf copies of articles to member authors. The office has also been maintaining the *Herpetological Review* index in Endnote and uploading pdfs of *Herpetological Review* to ZenScientist.com for SSAR member access. Breck suggests these duties (with the exception of maintenance of the EndNote Index) may be able to be moved to the Treasurer's office.

Breck indicates that, with ZenScientist.com closing, he does not know if online access to *Herpetological Review* can continue. It could be added to the SSAR website, but then someone would have to be in charge of membership. If it is online, it might be something the Treasurer could oversee, but Breck recommends they receive a budget for a part-time employee. Both the *Journal of Herpetology* page charges and the *Herpetological Review* duties currently have a budget for an employee.

The donated libraries that SSAR has received take up almost as much space as the publications inventory. Donations are much more difficult to process and sell, since each item is unique. Selling these donated libraries is time consuming. It might be possible to sell parts of them through an auction house. Breck thinks it is too time consuming to expect them to be sold on a volunteer basis, although it may be possible to offer them on eBay, if the person listing them is paid. That leaves the problem of what to do with items that do not sell.

George Pisani reported that he again filed SSAR's annual corporate report with the Office of the Kansas Secretary of State.

Editors' Reports

Co-Editors of *Catalogue of American Amphibians and Reptiles*, Chris Bell and Travis LaDuc, reported that two new *CAAR* accounts will have been published (open access at www.SSAR-CAAR.com) by the time the Lawrence meeting begins. Five additional accounts are in various stages of review. Chris and Travis continue to field inquiries for new accounts: one generic account and 16 species accounts have been claimed. They encourage potential authors to not only look at those species for which no accounts exist, but also at many of the published accounts: over half of all existing accounts are 25+ years old.

The co-editors assumed all of the editorial responsibilities in an effort to maintain the high standards of the series. They conservatively estimate that 80% of the citations they review require editorial changes. Many of these problem citations are for papers that were published in Latin American titles and journals. Chris and Travis continue to invest a large amount of time in acquiring and/or indexing significant holdings of published, but unindexed herpetological material. As a result, for some accounts under review they have found an additional 30 citations, helping to ensure that these accounts will be the authoritative reference for a given taxon. Chris and Travis thank the authors of the submitted accounts for their patience as they continue to refine their editorial process and incrementally add to their list of citations.

Kraig Adler (Editor, *Contributions to Herpetology*) reported that the revised and expanded version of *Contributions to the History of Herpetology*, vol. 1 was published in 2014. The original volume was distributed at the First World Congress of Herpetology in 1989 but has been out of print since 2000. The reprint is heavily annotated and includes six portraits that were missing in volumes 1–3, as well as corrections to all three volumes. There are also 96 new plates (mostly in color), with substantial captions.

Herpetology at Kansas: A Centennial History, by William E. Duellman, a detailed history of one of the most distinguished herpetological research and graduate education programs, was published in July 2015 and will be available at the KU meeting.

A grant from the Seidell Program at the Smithsonian was obtained to cover the translation of *Salamanders of Japan*, by Ikio Sato. SSAR will cover the formatting, printing, and binding costs and publication is expected in 2016. In various stages of preparation in this series are *A Guide to the Snakes of the Philippines* by Rafe Brown, Alan Leviton, Maren Gaulke, and Arvin Diesmos; *Field Guide to Amphibians and Reptiles of the West Indies* by S. Blair Hedges; and *Lizards of Southern Africa*, edited by William R. Branch and Aaron Bauer.

Aaron Bauer (Editor, *Facsimile Reprints in Herpetology*) notes that activity in 2015 continues to be associated with progress on the production of *The Collected Herpetological Works of Giorgio Jan*, with an introduction, annotated bibliography, and extensive systematic comments by Roy McDiarmid and Jay Savage. Material was received, edited, and initial layout was completed by late 2014. Authors' revisions, however, continued until early 2015 and editing of the completed new text is being finished now. The *Iconographie* was scanned by a commercial firm in San Francisco identified by the California Academy of Sciences, which has kindly provided partial funding for the scanning costs. However, extensive post-scanning modifications are still required. Original estimates of publication in 2014 have been revised to the last quarter of 2015.

Cantor's *Zoology of Chusan* (1842) and his *General Features of Chusan* (1842), together comprising 70 text pages and 11 leaves of color plates, represent an early treatment of the herpetofauna and other natural history of Zhoushan, Zeijiang Province, China, will be prepared as a facsimile give-away for the next World Congress of Herpetology, to be held in nearby Hangzhou, China in 2016. It is planned to print the book in China to avoid shipping costs and customs issues.

Aaron reports that work on *The Collected Herpetological Works of J. V. Barboza du Bocage (1823–1907)* and *The Herpetological Contributions of John Edward Gray* is still underway.

John Moriarty (Editor, *Herpetological Circulars*) reported that *Herpetological Circulars* 42 (*Herpetological Collecting and Collections Management, 3rd Edition* by John Simmons) was published in June 2015. There are no new circulars planned for later in 2015; however, John would like to convert several recent circulars to e-books.

Joe Mitchell, Editor of *Herpetological Conservation*, reported that, despite placing an ad in *Herpetological Review* requesting proposals for the *Herpetological Conservation* series, there have been no viable proposals since *Urban Herpetology* was published in 2008. Joe suggests that the Board should decide whether or not to cancel this series. The Board indicated a strong desire that the series not disappear, as it sends an important message about the Society's commitment to conservation. The Board indicated that publication does not need to be an annual event, and urged Joe to continue to think of possibilities for this series, including contacting colleagues at PARC.

Robert Hansen, editor of *Herpetological Review*, reported that Volume 45 consisted of 752 pages (a nearly 19% increase since the new format was adopted in 2011, and a far cry from when he took over as Editor in 1991). Personnel changes include the resignations of David Steen and Kyle Miller Hesed and the addition of Robert Mendyk, Chava Weitzman, and Travis Taggart. President Bauer indicated his intent to step down as book review editor for *Herpetological Review* and is looking for a replacement for this position.

Tiffany Doan and Paul Bartelt remain as co-Editors of *Journal of Herpetology*. Erin Muths and Gad Perry, as outgoing co-editors, continue to handle papers submitted in 2013 and before. The Associate Editor (AE) roster at the end of 2014 contained 22 continuing AEs: Neil Bernstein (US), Phil Bishop (New Zealand), Xavier Bonnet (France), Rafe Brown (US), Russell Burke (US), David Chapple (Australia), Steve Corn (US), Jennifer Gillette (New Zealand), Evan Grant (US), Brian Greene (US), James Harris (Portugal), Hinrich Kaiser (US), Nancy Karraker (US), Edgar Lehr (US), Marc Mazerolle (Canada), Frank Mazzotti (US), Rocky Parker (US), John Rowe (US), Christopher Salice (US), Stephen Tilley (US), James Watling (US), and Eric Wild (Brazil); all four Editors also function as AEs. R. Graham Reynolds (US) and Reid Tingley (Australia) came on as new AEs during 2014 and the first half of 2015. During the first half of 2015, Glenn Shea (Australia) resigned. Andrew Durso (US) served as a guest AE for a special section on detectability. Paul Andreadis remains the Index Editor for the journal. The Editorial Board gained one new member during the first half of 2015, Brian Sullivan. Brian Crother, David Cundall, William Dunson, David Green, Diana Hews, Joe Mendelson, III, James Petranka, Rick Shine, Gregory Watkins-Colwell, John Wiens, and Dawn Wilson remain from the past Board.

The addition of two new AEs has replenished the AE pool from the losses encountered during 2013. Tiffany and Paul are still looking to add one or two more AEs, especially those versed in squamate ecology, for which they receive a large number of manuscripts. They are especially interested in expanding representation from Brazil, a country that contributes many manuscripts each year, and from Asia or Africa, which are not represented.

A source of concern to Tiffany and Paul is the fact that overall submissions to *Journal of Herpetology* declined again in 2014. Submissions for 2015 (110 as of the end of May), however, are higher than the number submitted during the same period in 2014. The amount of time needed to reach initial decisions decreased in 2014, but the days from receipt to final decision remained high. Part of this can be attributed to reviewers not responding in a timely fashion. The wait between acceptance of a paper and publication averages 9-13 months. However, thanks to "Online First," readers have access to a near-final version almost as soon as a paper is accepted.

During 2014, the journal received submissions from 23 countries, which is lower than all of the years from 2009–2013, which had 33–48 countries represented. Tiffany and Paul believe this primarily reflects the decrease in the number of manuscripts. The leading countries from which manuscripts originate remain the USA (77) and Brazil (20), ranks both countries have held since data became available in 2006. During 2014, 67 amphibian and 114 reptile manuscripts were submitted (this was the first full year for which amphibian versus reptile submissions were tracked).

Over the past few years Tiffany and Paul have implemented a number of new features:

1. A new Aims & Scope for the Journal, in consultation with several Society members. It now appears on the journalofherpetology.org and the ssarherps.org websites.
2. A twitter account for the Journal, @JofHerp, which has over 300 followers at this writing.
3. Optional second-language abstracts (started for all languages in 2011), which are becoming more common.
4. Invited Long-term Perspectives (started in 2011)
5. Inclusion on the back cover of each issue (starting in 2012) of a world map indicating countries from which published papers are included.
6. Full-color, no-cost for graphics (option added 2013).
7. No page charges for SSAR members (starting in 2013).
8. Online-early appearance of accepted articles (starting in 2013) at journal website, Online First.
9. Associate Editor Lunch at SSAR annual meetings.

Standing Committee Chair Reports

The following SSAR members continued their service on the Conservation Committee in 2014–2015: Ross Alford, Nicole Angeli, April Barreca, John Jensen, Nancy Karraker, Karen Lips, Joe Mendelson, III, Gad Perry, Stephen Richter, Betsie Rothermel (Chair), and Susan Walls. During the past year, the Conservation Committee advocated for emergency measures to prevent introduction of a newly discovered chytrid fungus (*Batrachochytrium salamandrivorans*, or *Bsal*) responsible for die-offs of salamanders in Europe. Following publication in Fall 2014 of studies demonstrating the virulence of *Bsal* to North American salamanders, the Committee coordinated submission of a joint letter from four major herpetological societies (SSAR, ASIH, HL, and Canadian Herpetological Society) to U.S. Fish & Wildlife Service urging them to use their authority under the Lacey Act to suspend imports of salamanders and also to develop pathogen screening and certification programs to provide more comprehensive protection against introduction of amphibian pathogens. Unfortunately, the U.S. Fish & Wildlife Service has not taken any action to date. The other main focus was on a renewed effort to end the few remaining rattlesnake roundups in Alabama, Georgia, Oklahoma, and Texas. Joe Mendelson, III remarked that he had contacted some prominent companies listed as sponsors of some of these events. Their "sponsorship" apparently was (unwelcome) news to them. Joe suggested that SSAR consider writing letters to companies when their names are attached to such events. In the year ahead, the Committee is planning to engage with the zoo community and other herpetological societies in a broader push to convince the promoters and organizers to change the focus of remaining roundup events to be wildlife-friendly. Betsie Rothermel announced her decision to step down as chair and Joe offered to assume this position. President Bauer immediately accepted Joe's offer!

Joe Beatty, Chair of the Dean Metter Award Committee, received eight proposals for the Dean E. Metter Memorial Award. This year's winner is Carmen Harjoe, a Ph.D. student in the Department of Integrative Biology at Oregon State University. Her dissertation research deals with the status of populations of Western Toads (*Anaxyrus boreas*) in southeastern Alaska. Carmen is interested in determining if southeastern Alaskan populations of the toads are stable or declining. She will do this by determining toad site occupancy and abundance at localities where the toads are found and also whether the toads are infected with disease(s).

The 23rd annual Seibert Awards Competition (Rafe Brown, Chair) was run at the 57th Annual Meeting of SSAR in Chattanooga. There were 29 eligible presentations. The Seibert Award winners for 2014 were: Systematics/Evolution: **Elyse Freitas** (Villanova University), "Molecular phylogenetics and patterns of limb loss in the genus *Scelotes*." Ecology: **Chris Thawley** (PennState University), "The cost and benefits of adaptation: a case study using native fence lizards and invasive fire ants." Conservation: **Drew Davis** (University of South Dakota), "Effects of agricultural tile drainage on amphibians in eastern South Dakota." Physiology/Morphology: **Patrick Moldowan** (Laurentian University), "Turtles with teeth: tomiodont morphology and functional significance in the painted turtle (*Chrysemys picta*). All winners received a check for US $200 and a book from CRC Press.

Honorable mentions were: Systematics/Evolution: **Rachel Skinner** (Villanova University), "Phylogenetic relationships of South African geckos in *Pachydactylus geitje* species complex (Squamata: Gekkonidae)." Ecology: (A) **Meagan Thomas** (Eastern Illinois University), "Quantifying dietary overlap in a community of invertebrate feeding snakes;" and a *special undergraduate honorable mention* (B) **Mark Herr** (James Cook University), "Stressed snakes strike first: hormone levels and defensive behavior in free-ranging cottonmouths." Conservation: **Brian Crawford** (University of Georgia), "Does pride work? Evaluating an NGO's integrative model for promoting community conservation behavior." Physiology/Morphology: **Matthew Dickson** (California State University, Northridge), "Rapidly adapting to the neighborhood: physiological responses of Mediterranean house geckos to their introduced climates."

The members of the Herpetological Education Committee (HEC) this year were Craig Guyer (Chair), Scott Boback, Dora Pinou, Lynne Haugen, and Al Richmond. The biggest HEC project continued to be the Meritorious Teaching Award in Herpetology (MTAH), sponsored by SSAR, HL, and ASIH.

At the request of President Bauer, the committee also reviewed criteria for presentation of the pre-baccalaureate travel awards. The HEC revised the rules to restrict awards to students in grades 9–12 with an interest in herpetology. Applications will consist of a letter of interest written by the student indicating why they want to attend a herpetology conference and what their herpetological interests are, a letter of support from a teacher, and a letter from a parent or guardian indicating willingness to provide transportation and serve as chaperone for the student during the conference. The HEC then will review these materials and provide awards based upon overall strength of the application. Only applications received by April 30 of the year of the meeting will be evaluated. Applicants will be judged on financial need and academic maturity. There was some discussion of building an endowment to support this program once we have appropriate guidelines and an application process in place.

The HEC has instituted a system in which committee members have defined terms, during which each member eventually becomes chair and then cycles off the committee. This procedure is being implemented to provide greater institutional memory. Under this system, Scott Boback will become chair for 2016 and Craig Guyer will cycle off the committee.

The winning paper for the 2014 Kennedy Award (Lynnette Sievert, Committee Chair) is "The Relationships between Parasite Intensity, Locomotor Performance, and Body Condition in Adult Toads (*Rhinella ictericа*) from the Wild" by **Eduardo H. Moretti** et al., *Journal of Herpetology* 48:277–283. Eduardo will receive a check for $200 or $400 in SSAR publications.

Kraig Adler, Chair of the Long-Range Planning Committee (LRPC), reported that neither Past-President Aldridge nor current President Bauer has referred any items to the LRPC for discussion this past year, and the LRPC did not meet in 2014. However, an open meeting of the LRPC has been scheduled for the KU meeting.

The current LRPC has been active since September 2010. The Committee has accomplished a great deal over these last four years, but Kraig thinks it is time for a new committee to take a fresh look at SSAR: evaluate the changes that have been put in place since 2010 and consider new ideas to better secure our future as a vibrant, member-led and -oriented scientific organization that continues to be a pace-setter among the world's herpetological societies.

Kraig remarked that it was the LRPC (in 2011) that recommended SSAR to consider returning to holding occasional meetings on university campuses. The Board approved this recommendation and the LRPC followed through by endorsing a plan to hold the 2015 meeting at KU. We invited PARC to be our major partner this year. This is the first time that PARC has held a nation-wide meeting of its otherwise regional organizations. SSAR is very pleased that they have joined with us and we look forward to much cross-fertilization of interests and ideas by bringing SSAR and PARC together at KU.

The JMIH meetings remain SSAR's default arrangement for annual meetings and this is our main mode of operation for annual meetings. However, every 3–5 years (i.e., once during the career of most students) SSAR may choose to hold a different kind of meeting where students can interact more intimately with herpetologists, including our seniors, and do so at low cost. The KU meeting is a test of this new approach and the LRPC asked for feedback about the KU meeting at its open meeting in Lawrence. President Bauer commented that he has invited the Presidents of ASIH and HL to visit him later this year to talk about issues facing all three societies, including membership and meetings.

In his report, Rafe Brown (co-Chair of the Local Committee for the 2015 meeting) presented a draft of the meeting schedule. The Membership Committee was inactive in 2014. Former co-Chairs, Ann Paterson and Marina Gerson, suggest that the Committee needs clear objectives provided by society leadership and that the implementation of any recommendations be taken on by elected leaders. Ann has been in contact with the new Chair of this committee, Greg Watkins-Colwell. She will continue to communicate with him and include the members of the LRPC in the discussion.

In 2014, memberships in SSAR totaled 1,862, which is 145 fewer than in 2013. Regular memberships and student memberships continue as the two most important categories, numerically. Seventy-three percent of the 2014 members were continuing their memberships from previous years; of the 27% new memberships, some of these may have been members in prior years. In all categories of membership combined, 1,643 were print memberships and 219 were for online access only. Student members showed greater demand for online memberships, than did Regular members. The 2014 memberships represented herpetologists from 67 countries (up from 63 in 2013), but addresses from the United States made up 80% of all memberships. The next eight most-represented countries, ordered from the greatest number of members were Canada, Australia, Brazil, United Kingdom, Germany, Japan, Mexico, and the Netherlands. There were fewer than ten members from each of the other 58 countries.

PHOTO BY MARION PREEST

FIG. 37. Participants in the SSAR Mentor program.

The Mentorship Committee consists of Kris Kaiser (Chair), Andrew Durso, Joe Mendelson III, and Marion Preest. At the Tennessee meeting, the Mentorship Program paired 17 students from across the societies with mentors. Mentees in the program ranged from three pre-baccalaureate students to beginning Ph.D. students, and came from all societies. Mentees were all previous attendees of the meetings. Follow-up surveys showed a general satisfaction with the program. Joe Mendelson, III indicated that the program this year (2015) was smaller than usual, but very successful (Fig. 37). The Committee is debating whether to increase the size and scope of the program in the future.

Robert Espinoza, Nominations Committee Chair, reported that no election was held in 2015 and thus the Nominations committee was inactive. Members are asked to pass on suggestions of nominees for the 2016 election to the Chair.

Resolutions were presented at the SSAR Business Meeting in Chattanooga in 2014, and these have been published in *Herpetological Review*.

Josh Kapfer (Chair, Roger Conant Grants-in-Herpetology Committee) received 64 proposals. Most applications were in the "Laboratory Research" category.

The winners each received $500 and they are:

Conservation.—**Pamela Clarkson**, Southeastern Louisiana University, "Rehabilitation stress dynamics of incidentally caught Kemp's Ridley Sea Turtles (*Lepidochelys kempii*)." **Madeline Cooper**, Humboldt State University, "Examining invasive Bullfrog (*Rana* [*Lithobates*] *catesbeiana*) movement patterns on the Trinity River."

Education.—**Valentine Kheng**, Surya University (Indonesia), "HEAR: Hello Amphibians and Reptiles!!!"

The Andrew H. Price Field Research Grant-in-Herpetology.—**Samantha Rumschlag**, Miami University, "Toads in Peril? Assessing the risk of American Toad populations to an emerging infectious disease, chytridiomycosis." **Hannes Schraft**, San Diego State University, "Infrared prey sensing in rattlesnakes (*Crotalus* spp.)."

Laboratory Research.—**Sean Harrington**, San Diego State University, "Constructing the pitviper tree of life." **Alexander Novarro**, University of Maryland, "Will intraspecific variation buffer the effects of climate change in lungless salamanders? Measuring the effects of adult body size on the thermal physiology of *Plethodon cinereus* across an elevation gradient."

Travel.—**Kyle Hovey**, John Carroll University, "Alkaloid-based chemical defenses of the Strawberry Poison Frog *Oophaga pumilio*: do variable defenses provide equal protection from microbial pathogens? **John Phillips**, University of Tulsa, "Comparative genomics of eyes in spelerpine salamanders."

International.—**Ivan Camilo Beltran Arevalo**, University of Los Andes (Colombia), "Autoresistance to batrachotoxin (BTX) in *Phyllobates bicolor*: a molecular and physiological approach." **Saeed Hosseinian**, Ferdowsi University of Mashhad (Iran), "Biogeography and phylogenetics of the *Paralaudakia caucasia* species complex." (Because of current restrictions on sending funds from the U.S. to Iran, and despite prolonged efforts, we regret that SSAR has been unable to provide Saeed Hosseinian with his award. He has been informed that SSAR will retain the funds and, if policies change, the Society will be pleased to send him his award).

Undergraduate Research.—**Mark Herr**, Penn State University, "Thermoregulation and predation trade-offs by gravid Timber Rattlesnakes, *Crotalus horridus*, at gestation sites."

Since Spring 2013, the Website Subcommittee has been comprised of Carol Spencer (Chair), Michelle Koo, Raul Diaz, Vincent Farallo, Joe Mendelson III, and Todd Pierson. Carol reports that in the first year, the committee accomplished the ambitious goal of publishing a completely new website and content management system (http://ssarherps.org/). This went live 28 July 2014, in time for the SSAR/JMIH 2014 meeting. This completely revamped site benefits users as well as committee/ board members and editors, who needed an easily editable site that can be updated often.

Since the website went live, 32 blogs, news, events, and updates have been provided to the Latest News and Homepage Slideshow. The Subcommittee has edited many pages since the launch, and allowed specific individuals (editors, committee chairs, all website committee members) access to edit parts of the WordPress site themselves, so they can change and update their specific pages of interest. They are still working on streamlining these processes and have created some tutorials and guidelines specific to these tasks (e.g., Blog Guidelines).

Google Analytics is compiling some interesting statistics now that we have our first year tracked. For example, from 28 July 2014 to 14 Jun 2015, we have had ~41,000 sessions from new visitors to the site, viewing 2 pages per session, and ~16,000 visits from returning visitors, viewing 2.4 pages per session. Visitors reached us via various searches on Google, including "SSAR," "herpetology," "herpetologist," and "grants-in-herpetology" as the search terms that accounted for the most new sessions after unexplained search terms. The United States accounted for most users of the site, with Brazil, Canada, and United Kingdom the next three countries of origin for sessions. Peaks in usage occurred in July 2014 (when the site launched), and May 2015 (probably because of the SSAR conference abstract deadline).

The Subcommittee implemented backup services for the website and its content. Much of this and the Google Analytics required a gmail account and so we needed to 're-initiate' the previously dormant/lightly used ssarherps@gmail.com account. We are now regularly using this and checking it.

In 2015, the focus has been on implementing a completely new Common Names Database, which will have all the current updates from the taxonomic subcommittees from Brian Crother as of December 2014.

Some features of the site include: simple searches, loose (partial string searches) and fuzzy (close match) searches, searches by taxonomic group (e.g., snakes, turtles, etc.), and other advanced searches, such as clade, subtype, family, genus authority or species authority searches, searches on alien species and many other features. The resulting data displayed include genus, species, subspecies (when applicable), English name, images (links to CalPhotos when available), major common type (e.g., snake, salamander), English subtype, Linnean order, genus authority, species authority, and authority year. When you click on a row in the resulting database, you can view more information, such as taxon notes, authors and dates of the current taxon information, and links to other sites for more information about each species, such as iNaturalist, CalPhotos, the Reptile Database or AmphibiaWeb. Users will be able to download the entire database as a csv file.

As the Website Subcommittee finishes the Common Names Database pages, they plan to move into the next phase of responsibilities, hopefully reducing the editing and work load on most members. Website updates are easy to do with the new WordPress site, but they still require regular amounts of time and energy by various committee members. George Pisani suggested that the Board and other members of the society should be the ones generating content for the website, not necessarily the already-hardworking members of the Subcommittee.

Brian Crother (Chair) Standard English and Scientific Names Committee reported that Steven Tilley and David Wake stepped down last year and they have been replaced by Ron Bonnet and Elizabeth Jockusch. The professionals on the committee are thanked for their terrific work: Jeff Boundy, Frank T. Burbrink, Jonathan A. Campbell, Kevin de Quieroz, Darrel Frost, David Green, Richard Highton, John B. Iverson, Fred Kraus, Roy W. McDiarmid, Joseph R. Mendelson III, Peter A. Meylan, Alex Pyron, Tod W. Reeder, and Michael E. Seidel.

No report was received from the Student Participation Committee this year. President Bauer will be in touch with the new Chair, Jeremy Feinberg, about reactivating this Committee. The Board expressed a desire to increase student involvement (including pre-baccalaureate students) in the Committee. The names of several students were suggested and Aaron will pursue this.

The fourth annual SSAR Student Poster Awards (recently named the Victor Hutchison Student Poster Awards) were presented during the 57th Annual Meeting of SSAR in Chattanooga, Tennessee. We had 40 eligible posters. All awardees received a check for US $200 and a book from CRC Press. This was the first year the award was $200, double that in previous years. The winners are:

Physiology & Morphology.—**Krista Mougey**, Texas Tech University, "Thermal ecology and locomotor performance of the critically endangered stout iguana *Cyclura pinguis.*"

Conservation & Management.—**Grant Connette**, University of Missouri, "Historic timber harvest predicts abundance but not genetic diversity of a terrestrial salamander, *Plethodon shermani.*"

Ecology, Natural History, Distribution, & Behavior.—**E. Alexander Rohtla**, Villanova University, "Advertisement calls of the thick-toed geckos (Reptilia: Gekkonidae: *Pachydactylus*)."

This year's judges were Tiffany Doan (Chair, State College of Florida, Manatee-Sarasota), Marina Gerson (California State University, Stanislaus), Jon Davenport (University of Montana), Bruce Kingsbury (Indiana-Purdue University at Fort Wayne), Kristen Cecala (Sewanee-University of the South), Thomas Lozito (University of Pittsburgh), and Frances Irish (Moravian College).

In 2014, Mike Jorgensen and Vincent Farallo continued as co-chairs of the Student Travel Awards Committee. In 2014 the value of travel awards was increased from US $400 per award to $500. Fourteen applications were received for the 10 available awards of $500 to help fund student travel to the 2014 JMIH in Chattanooga. The main role of the Student Travel Awards Committee is to accept applications for the award and coordinate with the awardees to supervise the silent auction table at the annual meeting; Vincent Farallo was able to attend the meeting to direct awardees and oversee the silent auction table. Students receiving awards helped supervise the silent auction table as has been done in previous years. There will be 12 awards of $500 available for the 2015 SSAR meeting in Lawrence, Kansas to help cover the increasing cost of travel. Details of the travel award are presented on the new SSAR website and are regularly updated to ensure students have current information. Finally, Mike Jorgensen is stepping down from the Student Travel Awards committee. Vincent Farallo will continue as the chair of this committee.

Coordinators' Reports

Dan Noble, Election Officer, reported that 11 mail and 123 electronic ballots were received for the 2014 election. The following people were elected to their respective roles for 2015:

President-elect: **Rick Shine**

Treasurer: **Ann Paterson**

Secretary: **Marion Preest**

Board of Directors I (two people with highest votes): **Robin Andrews** and **Emily Taylor**

Board of Directors II: **Kim Lovich**

Board of Directors III: **Tony Gamble**

The Live Auction in 2014 was organized by Samantha Kahl, Greg Watkins-Colwell, Kirsten Nicholson, and Meredith Mahoney. This year Kirsten and Meredith stepped down from the committee at the completion of the live auction, having served for many years.

Greg reported that in 2014 the SSAR and HL Live Auction returned to the "normal" operation of generating funds to be split between SSAR and HL. Efforts were made to include as many different auctioneers (with different auctioning styles) as possible. Humor and "unique" items were also part of the night's festivities adding to the levity. The auction maintained a large audience late into the evening. Auctioneers for 2014 were Sara Ruane, Travis Hagey, and Sean Graham. Students assisting the live auction were Krista Mougey, Catriona Hendry, Elyse Freitas, Arianna Kuhn, and Rachel Skinner. Additional help was provided by Nathali Aall and Ross Maynard.

The Live Auction made $6,808. Expenses associated with the Live Auction continue to take a sizeable cut from the funds raised. The total profit following expenses was $4,855, which was split evenly with HL resulting in $2,428 to help fund SSAR student travel awards. The Board talked about the importance of members understanding "the point of the auction," i.e., to support students.

Greg confirms that he will step down from the Chair of the Auction Committee following the Live Auction at the 2015 SSAR meeting in Lawrence, Kansas. Samantha Kahl and Sean Graham will assume that role.

Al Savitzky, Representative to AIBS and BioOne, reported that as of this year, BioOne has published 1.1 million pages and has returned $32 million to its member publishers. The funds are returned in the form of both royalties and profit-sharing, and are based on an algorithm that reflects relative use of the journal within the collection. BioOne has merged its two collections (formerly known as BioOne.1 and BioOne.2) into a single collection for the purpose of sales (now known as BioOne Complete), and future sales will be only for the full collection. However, the two collections remain internally distinct, to protect the financial returns to the individual publishers.

Al described three presentations at this year's Publishers & Partners Meeting that may be of particular interest to our society members. First, an update was provided on BioOne's new journal *Elementa: Science of the Anthropocene*. This open-access journal continues to seek new manuscripts, and society members are encouraged to visit their website (https://www.elementascience.org/) to consider whether *Elementa* would be an appropriate outlet for their publications on human impacts on fauna or habitats.

Second, Amy Brand of Digital Science gave a presentation entitled "Beyond Authorship: An Introduction to the Credit Taxonomy." The presentation dealt with the increasing complexities of authorship and credit for scientific publications, including the issues of "coercion authorship" and "honorary authorship." She noted that a Committee on Publication Ethics (COPE) has been established in the UK, and other organizations are considering the implications of modern trends in authorship and credit.

Finally, Kathleen Erickson discussed the new joint editorial office for the American Ornithological Union and the Cooper Ornithological Society. Having failed to fully merge the several ornithological societies headquartered in North America, the AOU and COS did succeed in merging their editorial offices. Kathleen, who serves as Managing Editor for both societies' journals, discussed their joint publication office in detail. The goals, among other things, were to effect savings in publication costs and also to protect print publication for as long as possible. The two societies maintain separate Editors-in-Chief and Associate Editors, but they share a Managing Editor and her office, with both societies contributing equally to the costs of that office. Great care went into establishing the joint editorial office, which is overseen by a Joint Advisory Committee (for editorial policy) and a Joint Management Committee (for financial oversight). Many benefits have emerged from this relationship, including the online publication of a joint newsletter which is read by >10,000 people. This may be an appropriate model for collaboration among several of the herpetological and ichthyological societies. These and other presentations from the 2015 Publishers & Partners Meeting can be viewed at http://www.bioone.org/page/about/presentations.

Al reported that this year, AIBS has been re-examining its structure and reconsidering its core mission. Key to that mission will be a continuing commitment to the AIBS Public Policy Office, which provides direct communication between our societies and legislators and other lawmakers. AIBS continues to provide direct access to legislators on behalf of its professional society constituents. Society members are encouraged to consider signing up with the AIBS Legislative Action Center (LAC; http://policy.aibs.org/), which provides immediate alerts regarding relevant legislation and simplifies contacting individual legislators to express an opinion on those issues, many of which are related to conservation or the federal funding of science. This year the Public Policy Office was heavily involved in efforts to ensure re-authorization of the America COMPETES Act, which included funding for NSF.

This year two symposium proposals were submitted to Symposium Coordinator, Dick Durtsche, for SSAR sponsorship at the 2016 JMIH meeting in New Orleans. The first proposal

entitled "*Eco-Evolutionary Dynamics Across Taxa: Fishes, Amphibians and Reptiles*" was submitted by David M. Green and Andrew Hendry. This symposium will focus on evolutionary changes that can occur through varied ecological processes influencing phenotypic changes in natural populations. The second proposal entitled "*Digital Herp Information and Communication*" was submitted by Peter Uetz as the symposium organizer. This proposal was submitted as either a symposium or a workshop depending on how much hands-on activities the speakers wanted to offer. It identifies the importance of digital information as a currency in science from data collection to publication, and communications not only among scientists but also to the general public through social media or on-line publications. Both proposals were sent out for external review and the proposals and reviews were given to the Board for their consideration. The Board voted to support the first proposal above, but not the second in its current form. The Board recognized the potential importance of the second proposal and recommended that the organizer reach out to HL and ASIH for "buy in" and encouraged him to think about developing the ideas as a workshop for 2017.

New Business

The Board reviewed the JMIH 10-year, renewable memorandum of understanding (MOU). The version of the MOU submitted to the Board was ambiguous with respect to the "opt-out" clause (allowing SSAR to occasionally hold independent meetings with sufficient advanced notice) found in the previous version signed by SSAR. Once this ambiguity is rectified, the Board authorized President Bauer to sign it on behalf of the society. Future JMIH meetings are to be held in New Orleans (2016) and Austin (2017). A location for 2018 is yet to be determined. Cleveland (Ohio), Providence (Rhode Island), and Duluth (Minnesota) are being discussed. The Board was reminded of the World Congress of Herpetology (WCH) to be held in China in 2016. SSAR will have a presence at the meeting, but because it is not in North America, it will not substitute for JMIH.

The Board discussed restrictions on eligibility for Roger Conant Grants-in-Herpetology in light of difficulties encountered this year sending funds to an awardee in Iran. The Board decided that the wording of the announcement for these awards should be changed to indicate that we cannot send funds to international applicants hailing from countries to which monetary transfers are prohibited by the US government. The Board regrets having to make such a decision. The Andrew H. Price Field Research Grant-in-Herpetology will be renamed the Roger Conant Field Research Grant-in-Herpetology.

SSAR received a request from WCH to join in developing a Global Communication Network for Herpetologists. After some discussion it was determined that this was not necessary as many SSAR members are active in the WCH organization; however, it would be useful to provide WCH with the name of someone active on the SSAR website. Carol Spencer (Chair, Website Subcommittee) will recommend someone to President Bauer.

Discussion then turned to the issue of open access requirements increasingly faced by authors. For example, researchers in Canada who obtain funding from the Natural Sciences and Engineering Research Council are required to publish their work only in peer-reviewed journals that are freely accessible (i.e., open access) within 12 months of publication. In the USA, the National Institutes of Health, but not (yet) the National Science Foundation have a similar requirement. This has implications for researchers wanting to publish in SSAR journals. The Board talked about the potential financial costs of going open access and what a reasonable open access fee might be. Al Savitzky suggested that we seek advice from BioOne. The consensus was that we need a uniform policy, i.e., not something that is applied to a subset of our authors, but to all authors. The same policy, but not necessarily the same fee, would apply to individuals publishing in *Journal of Herpetology* and *Herpetological Review*. After discussion of waiving or reducing the fee for non-members, it was decided that we would not do this in light of the fact that we already waive page charges for members. President Bauer appointed the following individuals to an *Ad Hoc* committee to investigate this matter further—Breck Bartholomew, Al Savitzky, Bob Hansen, Tiffany Doan, and Paul Bartelt. They were charged with developing a policy to be considered by the Board. It was recognized that this policy would likely need to be evaluated regularly.

Breck Bartholomew received a request from EBSCO that databases be full-text searchable with non-EBSCO discovery services. To meet this library expectation, EBSCO requests permission to share the full text in their databases with third-party discovery vendors for searching but not display. Breck indicated that we receive very minor annual payment from EBSCO and recommended that we decline this request. The Board agreed.

The Board then turned their attention to several issues raised by the co-Editors of *Journal of Herpetology*. The Board approved a request for continued funding of lunches for Associate Editors who attend the annual meeting. Following discussion of a request to provide free pdf files to authors publishing in *Journal of Herpetology*, including the financial implications, it was decided that the editors will work out the details and then return to the Board with a proposal.

The *Journal* currently has a policy that authors are required to use standard common names for all USA, Canadian, and Mexican species. Tiffany and Paul report that they have not had pushback against the USA and Canadian names, but some authors oppose the Mexican names, which they claim are not the common names used on the ground and that the names lead to confusion. The Board indicated that such a requirement was waived a number of years ago. Finally, Tiffany and Paul reminded the Board that, in 2016, they will publish the 50th volume of *Journal of Herpetology* and they are soliciting ideas for how to commemorate this milestone.

There was some discussion of the very generous support that SSAR has received from the Carl Gans Charitable Trust. Kraig Adler indicated that the Trust's Advisory Board is likely interested in continuing their support of SSAR, particularly for programs that would not happen without their support.

President Bauer thanked Breck Bartholomew for his many years of selfless service to SSAR in his role as Publications Secretary. The Board then focused its attention on the implications for SSAR of Breck's upcoming resignation. There are multiple issues to consider and Aaron urged the Board to not necessarily think of them as all being linked. He indicated that things will need to change, as he does not believe that we can find one individual to take over all of the roles that Breck has served. For example, we will need to reduce our storage costs by decreasing the size of print runs of SSAR publications (and accepting that some items will go out of print), considering print-on-demand in some cases, and decreasing the volume of material stored. Breck currently has approximately 1,000 ft^2 of books. He aims to reduce this to 500 ft^2.

Allen Press could store back issues of our journals and ship them when replacements are requested or in the case of late membership renewal. Allen Press would charge us for this. Rather than SSAR referring to this as a penalty for late renewal, we could refer to it as a discount for early renewal. Breck's office currently handles page charges, indexing of *Herpetological Review*, and mailing of pdf files to authors. The Board felt we could find some individual(s) willing to take over these jobs. Breck said it would likely need to be a society member and he hoped this could be handled soon.

Dealing with membership duties is a major task and we will need a plan in place by Fall 2016. There tends to be a period of peak activity, typically December–February. Allen Press was discussed as possibly taking over this responsibility (they have handled our membership in the past), however they are expensive. Al Savitzky encouraged the Board to consider the model recently adopted by the ornithological societies as well as thinking about including non-US herpetological societies in a common membership office. Joe Mendelson, III mentioned a large "volunteer army" at, for example, ZooAtlanta and suggested that such groups may be willing to take on some of these tasks for the Society. Vinny Farallo indicated a need to integrate membership activities with the website.

Even if we are able to farm out many of these tasks, we will still need someone to handle the publications side of Breck's responsibilities. Pre-publicity of SSAR publications is done by the series' editors, but we still need someone to continue with the advertising, particularly if we hope to move inventory rapidly to save on storage costs.

Despite the issues that Breck raised in terms of dealing with donated libraries, Aaron encouraged the Society to be open to the idea of continuing to accept these. In wrapping up this discussion, Aaron reminded the Board that we will need to generate solutions to the issues of membership duties and back issues of publications between now and the 2016 JMIH. He indicated the importance of involving the LRPC, and tasked Breck with disposing (preferably selling) of donated items and reducing the square footage of books.

The Board then turned to the 2016 budget. A balanced budget of $299,250 for 2016 was approved by the Board.
The meeting was adjourned at 1547 hrs.

LRPC Open Meeting

An open meeting led by the Long-Range Planning Committee (LRPC) for all SSAR members was held on the afternoon of August 2nd. Discussed were: (1) evaluation of having occasional annual meetings on a university campus, and (2) future development of the newly redesigned SSAR web page.

SSAR Business Meeting

The Annual SSAR Business Meeting was called to order by President Bauer (1635 hrs, Aug 2nd). Over 150 members of SSAR were present. Officers, Editors, and Committee Chairs who were at the Business Meeting introduced themselves to the other attendees and gave brief summaries of their annual reports and relevant information from the Board Meeting.

Stu Nielsen read the following resolutions: "SSAR wishes to thank a large number of individuals for service and other contributions to the Society. First and foremost, we thank the members of the local committee who have put on such a fun and successful meeting. It's truly been a monumental amount of work. We wish to particularly acknowledge Rafe Brown, Rich Glor, and Kraig Adler, also George Pisani, Bill Duellman, and Linda Trueb. Thanks to the hordes of local students who have been involved for months in planning for this meeting as well as associated organizations—Partners in Amphibian and Reptile Conservation, Center for North American Herpetology, Kansas Herpetological Society, Missouri Herpetological Association, Arkansas Herpetological Society, and International Society for the History and Bibliography of Herpetology. We are grateful to Stacey Walters, Kevin Curry, Justine Hamilton, Sharon Leatherman, Jeremy Whetstone, and Jennifer Schmitendorf. SSAR is very pleased to have the following Senior Herpetologists in attendance at the 2015 Annual Meeting: Victor Hutchison, Bayard Brattstrom, Alan Leviton, Bill Duellman, Itzchak Gilboa, and David Wake. We greatly appreciate their presence. Thanks to Dave Dennis and Eric Juterbock for the updating and resurrection of their AV shows which had been missing from SSAR meetings for far too long. Thanks to this year's President's Travelogue speaker, Miguel Vences for his talk "Inventory of an Imperiled Paradise: Two Decades of Herpetology in Madagascar." The fact that it was essentially standing-room only attested to the popularity of this event. SSAR is immensely grateful to the Carl Gans Charitable Trust for their generous contributions to SSAR student members. The Trust covered the meeting registration fees for 20 students and provided $500–$1000 contributions towards travel costs of attending the meeting for an additional 11 students. SSAR, and especially Treasurer Ann Paterson, wishes to thank John Psaltos for many years of service as SSAR's accountant. We welcome Beverly Powell as our new accountant. Editors of *CAAR*, Travis LaDuc and Chris Bell particularly thank Bob Powell and Breck Bartholomew for their persistent help navigating through the logistics of editing this series. Kraig Adler wishes to acknowledge a grant from the Seidell Program at Smithsonian Institution to cover the translation by Richard Goris of *Salamanders of Japan* that is in Kraig's *Contributions to Herpetology* series. Robert Hansen, Editor of *Herpetological Review*, thanks David Steen (Section Editor, Natural History Notes) and Kyle Miller Hesed (Copy Editor) for their excellent service. Betsie Rothermel is stepping down as chair of the Conservation Committee after many years in this role. Thanks to Betsie and also to Joe Mendelson, III who has offered to assume this role. We thank Craig Guyer who has been chair of the Herp Education Committee for the past two years and will now be replaced by Scott Boback. A huge thanks to Vic Hutchison for the generous donation of his library to SSAR. This has allowed us to fund the Student Poster Awards program, which we have gratefully named after Vic. SSAR acknowledges John Sulzycki of CRC Press for his continued support of the Seibert Student Awards and the Victor Hutchison Student Poster Awards. Mike Jorgenson, co-chair of the Student Travel Awards Committee has resigned after several years of service. Thankfully, Vinny Farallo is willing to continue chairing this important committee. The society joins Greg Watkins-Colwell in thanking Kirsten Nicholson and Meredith Mahoney for their efforts on the Live Auction Committee for many years. Greg will continue to chair this committee through the end of 2015. Congratulations to the sixth winner of the SSAR/HL/ASIH Meritorious Teaching Award in Herpetology, Dr. Brad Shaffer. Thanks again to those who were part of the Mentorship Program and served as mentors for students attending this meeting. Finally, thanks to Carol

FIG. 42. Aaron Bauer presents SSAR Presidential Award for Lifetime Achievement in Herpetology to Kraig Adler for outstanding service to herpetology.

Spencer, Michelle Koo, Raul Diaz, Vincent Farallo, Joe Mendelson III, and Todd Pierson on the Website Subcommittee, as well as members of the Standard English and Scientific Names Committee for their efforts in getting the names database on the beautifully redesigned SSAR website.

Henri Seibert Best Paper, Victor Hutchison Student Poster, and Student Travel Awards were presented by Rafe Brown, Tiffany Doan, and Vinny Farallo, respectively (Figs. 38–40).

President Bauer then presented "SSAR Presidential Awards for Lifetime Achievements in Herpetology" to Tom Beauvais, Bob Hansen, and Kraig Adler. The award to Tom mentioned "his comprehensive research on the Eastern Massasauga," and "leading important innovations in SSAR's quarterly journals." Bob

was acknowledged for his "25 years as editor of *Herpetological Review* and his commitment to the conservation of amphibians and reptiles of California." The award to Kraig acknowledged his "outstanding service to herpetology as founder and dedicated officer, editor, advisor, and member of the Society for the Study of Amphibians and Reptiles." These awards barely scratched the surface of what the Society owes to these hard-working and dedicated individuals (Figs. 41, 42).

Al Breisch, co-Chair of PARC, thanked SSAR for the invitation to participate in such a successful annual meeting. President Bauer adjourned the business meeting at 1740 hrs.

CURRENT RESEARCH

The purpose of Current Research is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Ben Lowe or Chava Weitzman; e-mail addresses may be found on the inside front cover.

When it Comes to Size, Does Climate Matter?

Bergmann's Rule, where bodies tend to be bigger in colder environments, is well documented for mammals and birds. However, results from studies of ectotherms have been conflicting and controversial. The authors of this paper address whether there are relationships between body size and various climatic variables in amphibians of Europe and North America north of Mexico. To accomplish this, they gathered distributional and body size data for nearly all relevant species. They also amassed temperature, seasonality, net primary productivity, and

precipitation data for the regions. The authors employed three methods of analysis (orders analyzed separately). First, they conducted a grid cell analysis by dividing the region into cells, determining median body size and species richness for each cell, and assessing correlation with the environmental data using simultaneous autoregressive models (a regression method for spatial data). To investigate the importance of species richness, they simulated random-draw species assemblies (same dimensions as the empirical data; selection probability proportional to range size) and calculated a 95% confidence interval of median body size per richness value; this was compared with the empirical data. Finally, they performed a phylogenetic generalized least square (PGLS) regression using published phylogenetic relationships to determine whether they could detect correlations between distributional climate variables and body size. The grid-cell analysis found that for both orders, richness, mean temperature, and temperature seasonality were all correlated with body size. Median body size of both orders decreased with increasing richness. However, as temperature and temperature seasonality increased, anuran body size decreased, while caudate body size increased. Importantly, when all variables except richness are excluded from median body size models, the pseudo-R^2 values decrease little, suggesting that median body size is not strongly predicted by climatic variables. Further, median size fell mostly within the 95% confidence intervals based on random assignment. The PGLS analyses resulted in opposite, though weak, trends from those of the grid-cell analyses. These results overall support the importance of species richness in body-size clines found among Anura and Caudata. The opposite trends between these orders also indicate that a general rule cannot be assumed for climatic impacts on evolution of ectothermic body size. The authors acknowledge weaknesses in both of the methods in this study. Neither method incorporates variation in size across a species distribution, though a grid-cell analysis could be altered to discern population-level changes. Also, incorporating a larger geographical area could help detect other mechanisms relevant to patterns of body size in vertebrate ectotherms.

Extreme Resistance to Toxins by an Unknown Mechanism

Tetrodotoxin (TTX) is a chemical weapon found in many animal taxa and is known to block the movement of sodium across cell membranes. Few species are able to feed on animals with TTX and able to tolerate its effect. Snakes include some of the only species that regularly consume such toxic prey, and here, the authors present findings on the Eastern Hog-Nosed Snake (*Heterodon platirhinos*) and its occasional toxic prey, the Eastern Newt (*Notophthalmus viridescens*). In most systems, TTX resistance in a predator results from changes in the structure of the outer pore of the sodium channel. Through mutations in the genes coding for the outer pore protein, many species have converged upon TTX resistance. In the present article, the authors were interested in levels of TTX in newts and TTX-resistance in hog-nosed snakes where they live in sympatry and allopatry. They assayed both newt and snake phenotypes, as well as the functional genotype of the gene encoding the skeletal muscle sodium channel (*SCN4A*). Prey assays included measurements of TTX in newt skin and extrapolating measurements to the whole animal. For predator assays, snakes were injected with 1 and 10 mass-adjusted mouse units (MAMUs) for species allopatric and sympatric with newts, respectively, with serially increasing doses. Snakes were subjected to performance trials of sprint speed to calculate the required dose for a decrease in sprint speed by 50%. While newts from the two sampled sites did not possess significantly different levels of TTX, the snake populations tested (sympatric: 8 *H. platirhinos* localities; allopatric: one *H. platirhinos* locality and one *Heterodon nasicus* locality) had extremely different levels of resistance. The allopatric snakes had similar TTX resistance to other snakes lacking resistance. Alternatively, sympatric snakes were able to resist high doses of TTX, some to an extent that would kill most other terrestrial vertebrates. Surprisingly, the *SCN4A* allele of all the *Heterodon* was the same as the wild type found in non-resistant snakes, lacking any of the predictable mutations present in other resistant species. Thus, these snakes are able to consume some of the most toxic prey and are protected by mechanisms not yet known. It may be that these snakes co-opt mechanisms already present that protect them from their own venom to capture TTX. Whatever the mechanism, the convergence of phenotype on TTX-resistance has resulted from multiple paths.

Sleep with One Eye Open

Unihemispheric sleep is when an organism sleeps with half of its brain at a time, and this type of sleep could allow individuals to maintain vigilance or group structure while also getting those much-needed hours of rest. Some species able to use unihemispheric sleep include birds and aquatic mammals. One hint toward use of unihemispheric sleep is unilateral eye closure (UEC) of the eye associated with the hemisphere of the brain that is awake. The open eye could be used to detect potential threats or conspecifics; species that thrive in groups could use UEC to maintain group cohesion. Many reptile species exhibit UEC, including many turtles and lizards and some crocodilians. To explore the evolutionary history of UEC between birds and reptiles, the authors of this paper investigated the use of UEC in juvenile Saltwater Crocodiles (*Crocodylus porosus*). They conducted experimental trials for eye closure before, during, and after exposing the crocodiles to conspecifics and humans. While UEC was not common in baseline measurements and did not increase in the presence of a conspecific, the open eye did tend to be directed toward the visible crocodile, when present. In the presence of a human and immediately following presentation, crocodiles exhibited UEC a greater proportion of the time. Again, the open

eye was directed toward the human or where the human had stood. Periods of UEC more frequently involved an open right eye than left eye; in birds, the visual system is lateralized, with the right eye/left side of the brain better able to detect changes in the environment, and further studies are required to determine whether this is the case in crocodilians as well. These results agree with past studies of *Sceloporus* fence lizards. The authors discuss the possible evolutionary origins of UEC in reptiles, potentially arising as early as stem amniotes. Although these data suggest unihemispheric sleep, electrophysiological recordings should be conducted to determine whether unihemispheric sleep coincides with UEC in the case of the saltwater crocodile, and understanding the brains in more detail would also help to elucidate the evolutionary history of unihemispheric sleep in these organisms.

Continental Islands and Marine-Tolerant Frogs: A New Spin on Island Biogeography

One prediction of island biogeography is that islands that are closer to the mainland or are larger should contain more genetic diversity. Specifically, islands that are larger can maintain larger populations, and therefore more genetic diversity, and both larger and closer islands will receive more migrants, boosting genetic diversity. The frog species *Thoropa taophora* (Cycloramphidae) is endemic to Brazil's Atlantic Coast and adjacent continental islands, and has a high tolerance to salt. Here, the authors wanted to see if they could detect the signal of vicariance in these populations, and see if genetic diversity in these frogs matches the expectations from island biogeography. The authors collected frog samples from 7 coastal and 10 island sites, representing 9–49 frogs per site and used nine microsatellite loci to answer these questions. Results indicate that some expectations from island biogeography theory may not be applicable to recently isolated continental islands. Although the island populations had less genetic diversity, as one would expect from isolation and drift, the predicted effects of land area and distance to the mainland were not found in this study. STRUCTURE analysis separated the 17 sites into eight genetic demes, with nearby populations grouping into the demes and low admixture among the demes. Island area and distance to the mainland did not correlate with maximum likelihood estimates of island population sizes. Maximum likelihood estimates of migration rates detected migration in both directions between island and mainland populations, and migration rates near zero among most neighboring coastal populations. Analyses also estimated similar times since divergence among coastal and island populations. The authors discuss two processes that could lead to such results of genetic diversity: continued migration and the possibility of different genetic signatures for vicariance and founder events. With a small, salt-tolerant frog species, it is possible that islands more so represent a habitat fragment, where total area available may be less important than suitable habitat. A similar study with larger-bodied organisms may result in expected interactions of island size and genetic diversity. Additionally, in species such as *T. taophora* with high tolerance to salinity, or in species where the islands are within possible dispersal ranges, distance between island and mainland may have to be larger in order to detect expected effects of distance on evolutionary patterns. For conservation, this study detected low effective population sizes and low gene flow in the northern populations, indicating that those populations and populations of other species that share that habitat may be of considerable concern for conservation.

Skinks and Salt Secretions in Extreme Habitats

In extreme habitats such as desert or marine areas, species require adaptations that allow them to maintain homeostasis or tolerate fluctuations into an homeostasis in the face of fluctuating water and ion availability. Some species secrete concentrated stores of ions at once to minimize water loss, while others have salt glands that allow them to regulate ion concentrations. The paper described here is the first to investigate salt secretions in skinks that inhabit intertidal zones to determine how they cope with the high ion levels from their diet. The authors use a variety of techniques to study two populations of Suter's Skink (*Oligosoma suteri*) northeast of Auckland, New Zealand, with differing available habitat in terrestrial and intertidal zones. Measurements detected diet composition (stable isotope analyses) and nasal and cloacal salt secretions, as well as fecal water loss. Fecal samples included those from wild-caught diets and after laboratory feeding experiments. Skinks and invertebrate prey items were caught in four habitat zones, ranging from closer to farther from the ocean. The authors estimated proportional contribution of prey items to diets by fitting a Markov chain Monte Carlo model to the stable isotope data. At the site with less available vegetation, stable isotope analysis detected the main food source for the skink to be a type of amphipod, while skinks at the second site seemed to have a more balanced diet among prey items along the gradient from the ocean. This supports the authors' hypothesis that when a wide variety of food sources are available, the skinks will use both intertidal and vegetation zones for feeding. This pattern seems to have changed in recent years at one site studied, possibly due to the eradication of invasive predators in the area that may have limited the skinks' usage of the more terrestrial zones. Interestingly, the stable isotope analysis detected a separation between larger and smaller skinks and how they use the intertidal and terrestrial habitats; smaller skinks seem to forage more in the intertidal zone, while larger skinks consume more prey in the terrestrial areas. Generally speaking, these skinks excreted sodium predominantly through nasal secretions and urine, and potassium via feces. Amounts of ions in nasal secretions varied widely, but were comparable to those in other intertidal lizards. In the intertidal habitat, excess sodium is the limiting factor in a diet. This skink's ability to secrete sodium via multiple methods and in varying amounts may allow it to exploit multiple habitats and have a flexible diet. As this is the first

report on intertidal skink ion secretions, the authors end with a note that follow-up studies should include additional laboratory experiments with different salt-loads, as well as further experiments on the ontogenetic differences in diet composition and habitat use.

Janssen, J., D. R. Towns, M. Duxbury, and I. M. A. Heitkönig. 2015. Surviving in a semi-marine habitat: dietary salt exposure and salt secretion of a New Zealand intertidal skink. Comparative Biochemistry and Physiology, Part A 189:21–29.

Olive Ridley Sea Turtle Reported in the Mediterranean

This paper documents the stranding of an Olive Ridley Sea Turtle (*Lepidochelys olivacea*) in one of the northern-most occurrences of Olive Ridleys, and the first occurrence in the Mediterranean Sea. In May 2014, a sea turtle was stranded ashore on the Mediterranean coast of Spain, just north of 40° latitude. The authors used morphological characteristics to determine this turtle to be in the genus *Lepidochelys*, and DNA sequencing of a control region of mitochondrial DNA to identify the species. The individual's haplotype matched the Atlantic populations of Guinea-Bissau, Surname, and Brazil, as opposed to the other Atlantic and Pacific populations. The authors discuss two possible migration routes leading to the Mediterranean. The first is travel from South America northeastward across the Atlantic. The second route could be northward from the west coast of Africa. The paper discusses the likelihood of increased research and rescue efforts to help detect more individuals outside their circumtropical distribution, particularly in the eastern Atlantic, where data are sparse.

Revuelta, O., C. Carreras, F. Domènech, P. Gozalbes, and J. Tomás. 2015. First report of an olive ridley (*Lepidochelys olivacea*) in the Mediterranean Sea. Mediterranean Marine Science 16:346–351.

Though They Can Be Quick, Caecilians May Evolve Slowly

Though the genomes of anurans and caudates have been evaluated extensively, the genomic architecture of caecilians is relatively unknown. Studies of caecilian genomes, therefore, can provide insights into genome evolution in amphibians and tetrapods. As full genome sequences are not available for caecilians, the authors of this paper studied Hox genes, as they include pivotal information regarding organismal form and development, and gene function is known to rely on both coding and non-coding sequences. Thus, changes in Hox gene sequences are thought to have important impacts on major structural evolution of organisms. In addition to the sequences themselves, identifying patterns in Hox gene clusters can hint toward patterns in the rest of the genome of the organism. The authors used a combination of previous PCR surveys, long-range PCR, and genome walking to compile sequences for the majority of the four Hox clusters in the Banna Caecilian (*Ichthyophis bannanicus*). The caecilian Hox gene clusters were compared with those of other vertebrates to investigate phylogenetic patterns of conserved non-coding elements and repetitive elements. Rate of evolution was estimated using Tajima's relative rate test (RRT) to determine how that of caecilian compares with those of other vertebrates. The RRT detected that over 62% of caecilian's Hox coding sequences had slower evolutionary rates than the Western Clawed Frog, and over 80% evolved slower than humans, while the reverse of these was never true. General rates of evolution in the caecilian were similar to those observed in the Indonesian Coelacanth, which is considered to be a slowly-evolving species, and seven caecilian Hox genes evolved faster than their equivalents in the coelacanth. In the RRT analyses for proteins, one protein in frogs evolved slower than its analog in caecilians. Phylogenetic studies detected similar patterns. The *HoxC1* gene was present in the caecilian sequence, but absent in the rest of tetrapods, indicating that this gene was lost in the remaining tetrapod lineages. The *HoxD12* gene is also lost or has become a pseudogene in the caecilians and frogs analyzed. Snakes and lungfish also lack this gene, and it's thought the gene is connected to the reduction of digits in amphibians. This is either not the only path, or not the main component of digit reduction, however, as *HoxD12* is present in many limbless lizards. The authors leave us with many directions to head toward for future studies. What is the role of *HoxD12* in digit reduction? Who will sequence the intergenic gaps of this study to further understand the compact, minimalistic nature of caecilian's Hox clusters? And will further genome sequencing for caecilians corroborate the story of their slow evolution?

Wu, R., Q. Liu, S. Meng, P. Zhang, and D. Liang. 2015. Hox cluster characterization of Banna caecilian (*Ichthyophis bannanicus*) provides hints for slow evolution of its genome. BMC Genomics 16:468.

Hard Egg Shells: Rare but Beneficial in Gekkotans

The parchment-shelled eggs of most squamates are highly permeable to water vapor from the environment, and thus, these eggs are laid underground where conditions allow for water uptake. However, species in the gecko clade made up of the families Gekkonidae, Sphaerodactylidae, and Phyllodactylidae lay rigid-shelled eggs, which are less permeable to water vapor. These eggs are generally laid above ground, in drier environments. There are multiple fitness costs to laying rigid-shelled eggs for these gekkotans, including small hatchling size and the need for provisioning the egg with all the water necessary for embryo development. This clade accounts for 85% of gecko diversity, suggesting rigid eggs might be a key innovation that has allowed these geckos to be remarkably successful despite the apparent costs. Here, the authors examine the role of nest

moisture and temperature conditions on egg survival and hatchling phenotype. The study organisms, *Chondrodactylus turneri* (Gekkonidae) and *Eublepharis macularius* (Eublepharidae), lay rigid-shelled and parchment-shelled eggs, in dry and moist environments, respectively. Eggs were incubated at 25°C, 28°C, and 31°C, with low (*C. turneri* only) or high (both species) moisture. When exposed to low moisture conditions, *C. turneri* eggs had survival rates of over 90% at all temperatures, higher than the two lower incubation temperatures for both species incubated with high moisture. Egg survival was temperature-dependent in high moisture conditions, and death of eggs was linked to fungal infection. *C. turneri* eggs had varied amounts net water exchange depending on incubation moisture, not temperature. Values ranged from -15% to +0.4% initial egg mass, while *E. macularius* eggs increased up to 28% egg mass in high moisture conditions. The uptake of water in rigid-shelled eggs can cause shell cracks, increasing likelihood of fungal infection. In *C. turneri*, embryos incubated with high moisture did not utilize all of the yolk, and hatchlings were relatively smaller. They also selected relatively lower body temperatures if incubated at with high moisture or 31°C as opposed to 28°C. However, incubation temperature and moisture did not correlate with growth rates in the first 60 days. Egg survival in both species was highest in conditions most similar to natural nest conditions. When incubated in high moisture environments, *C. turneri* egg survival decreased and embryo development was slower, likely due to embryos competing for space in the egg with water, and fungi infecting cracked shells. As conditions ideal for these rigid-shelled eggs are poor for parchment-shelled eggs, and previous studies have found the opposite to be true as well, the authors discuss the likelihood that harder eggs enabled development in dryer environments, and brought an escape from infection. They may also provide more physical protection of the embryo. Higher survival of also allows for smaller clutches, possibly also offsetting the costs of calcium and water for each egg.

Andrews, R. M. 2015. Rigid shells enhance survival of gekkotan eggs. Journal of Experimental Zoology 323A:607–615.

Everybody Poops… Nematodes, If You're a Galápagos Giant Tortoise

The Galápagos Islands have unique flora and fauna that have been impacted over the years by the introduction of non-native species, overexploitation, and habitat loss. The Galápagos Giant Tortoise (*Chelonoidis nigra*) species complex included 10 species with a total population size of approximately 250,000 before the arrival of humans to the region. Seven species remain, with a total of 6,000–20,000 individuals. Though much of these species' ecology has been studied, their internal parasite communities have been largely ignored. Parasites can be important drivers of population fluctuations and diversity of their hosts and communities. In this paper, the authors report on the nematode community of tortoises from four wild populations and three captive breeding centers, to identify important nematode taxa, a measure of abundance, and patterns across the islands. Parasites were collected from fecal samples; egg density was measured using a modified McMaster method, and when available, expelled nematodes were identified using morphology and sequence data. The authors collected one fecal sample from 362 individual tortoises, representing six tortoise species. Nematodes were present in all populations except the captive tortoises on San Cristobal. Over 80% of the wild tortoises were infected. Nematode community composition differed by tortoise species, co-varying with island. Egg analyses detected five nematode types, representing four superfamilies. Two types of strongyle eggs were detected by visibly different egg sizes; the large type was found in all of the populations with nematodes, while the small type was only found in the two populations from Isabela Island. Trichurid eggs were found in all infected populations except the one on Pinzón Island. Infected samples had 1–404 eggs per gram, and over 90% of the eggs counted were strongyle eggs. Two nematode genera were identified from adults expelled in the feces of Santa Cruz tortoises, representing types not represented in egg counts, as these species hatch in utero. Neither sex nor relative tortoise age classes (old vs. young) had differing prevalence or mean abundance of nematodes. For wild tortoises, though prevalence was high, egg counts were relatively low. The authors provide data for present background levels of nematode parasitism in some Galápagos Giant Tortoises, and urge that more precise measures would give further insight into the evolutionary history of these host-pathogen interactions. The field would benefit from more detailed information on parasite species present, better measures of species abundance over time within individuals and populations, and a better understanding of how fecal parasites correlate with internal parasite load. The authors also urge conservation measures to be more mindful of parasites when housing and releasing tortoises in and from captive breeding sites, to avoid possibly detrimental introductions of new parasites into populations.

OBITUARIES

Herpetological Review, 2015, 46(4), 716–719.
© 2015 by Society for the Study of Amphibians and Reptiles

Douglas Athon Rossman 1936–2015: The Gentle Renaissance Man of Herpetology

Douglas Athon Rossman passed away on 23 July 2015 in Decorah, Iowa, of complications from a long battle with muscular dystrophy. Doug was born on Independence Day in 1936 in Waukesha, Wisconsin, the elder son of Vernon and Josephine Rossman. He is survived by his first wife Nita, his younger brother Will Rossman, his two children, Chuck Rossman, of Greenwell Springs, Louisiana, and Kathleen Rossman, of Baton Rouge, Louisiana, and nine grandchildren, and his second wife Sharon (married on 5 May 1990), her three sons Eric, David, and Doug Bates, and their four children.

As a young boy, Doug lived in Peoria, Illinois, and later in Kankakee, Illinois, before moving with his family to Coatsville, Pennsylvania, in the later 1940s. The family then moved to Hopewell, New Jersey, and Doug attended Princeton High School, in nearby Princeton, New Jersey. During these early years, Doug was a counselor at summer camps run by the Young Men's Christian Association, for which organization his father was an administrator. This was a formative period for Doug, offering an opportunity to both study nature and to educate young people. He was fond of accompanying his father to the camp during the off-season, where he was released into the woodlands to catch box turtles and water snakes. Perhaps as importantly, the time he spent alone in the woods allowed him to contemplate nature in a spiritual manner that molded his quiet demeanor and guided his creative writing in later years. Living in New Jersey also placed Doug in the proximity of the Philadelphia Zoo, where he met its Reptile Curator Roger Conant. Conant had a research interest in natricine snakes, which also became Doug's lifelong focus of academic research. When time came for college, Doug enrolled at Southern Illinois University in Carbondale, Illinois, where he was graduated in 1958 with a B.A. degree in zoology. At SIU, he held a position as an undergraduate research assistant from 1956–1957, and while there he married his first wife, Nita. Soon thereafter, he moved to the "Land of Sunshine" and enrolled in the graduate program at the University of Florida in Gainesville. Doug bypassed the M.S. degree, going straight for the Ph.D., co-advised by Archie Carr and William Riemer, which he was awarded in 1961. At UF, he functioned as a graduate teaching assistant from 1958–1959.

Doug's first academic position was as an interim instructor at the University of North Carolina in Chapel Hill from 1961–1963. In 1963, Doug accepted a position as an assistant professor at Louisiana State University at Baton Rouge, where he remained for the remainder of his academic career until his retirement in 1998. He moved up through the ranks steadily, becoming a full professor in 1976. Doug was also responsible for the curation of the herpetological collections at LSU, starting as an assistant curator in 1963 and becoming curator in 1976, coincidental with his move through the professorial ranks. During his curatorial tenure, the herpetology collection increased from roughly 8,000 to a little over 80,000 specimens, and due to his interest in snake anatomy, he built into it the world's largest collection of snake skeletons.

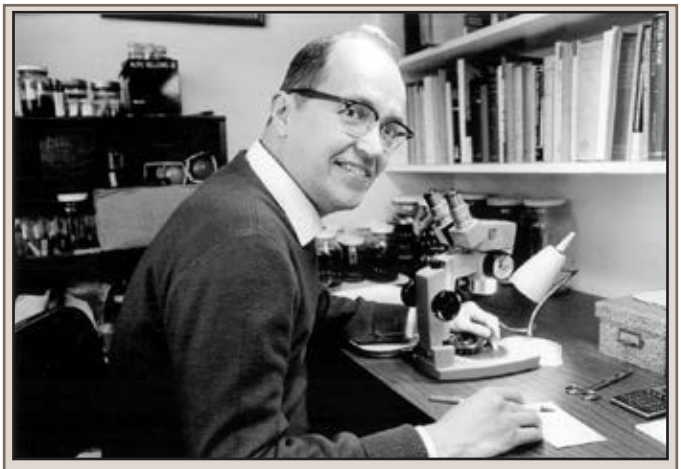

PHOTO BCOURTESY OF LSU MUSEUM OF NATURAL HISTORY

FIG. 1. Douglas A. Rossman, ca. 1980, in his office at the Louisiana State University Museum of Natural Science, Baton Rouge, Louisiana.

Doug built a strong research presence in herpetology from an early stage of his academic career. His first paper, a two-pager on food habits of a captive *Seminatrix* [now *Liodytes*] *pygaea*, appeared in 1956, when he was 20 years of age. Thereafter, Doug produced a steady output of publications, with at least one paper appearing each year, with the exception of very few years. Over the course of his publishing career, he produced 98 scientific publications, including two books.

Doug's central research interest involved the systematic study of snakes, most notably those belonging to the natricid genus *Thamnophis*, but also other related genera in the United States and Mexico (*Adelophis*, *Clonophis*, *Liodytes*, *Nerodia*, *Regina*, *Storeria*, *Tropidoclonion*, and *Virginia*). His work on *Thamnophis* culminated in a book—*The Garter Snakes: Evolution and Ecology*—coauthored with Neil B. Ford and Richard A. Seigel and published in 1996. These authors recognized 30 species in the genus; currently, 34 are recognized at the Reptile Database website. Interestingly, the four species described subsequent to the appearance of the *Thamnophis* book either were described by Doug, in collaboration with Frank Burbrink, or were named for Doug, by Roger Conant. Doug and Frank named *T. bogerti*, *T. conanti*, and *T. lineri*. Roger Conant named *T. rossmani*, which was truly an appropriate patronym, given Doug's longtime devotion to this genus. Doug also considered Roger Conant as his mentor, as evidenced by his dedication in the *Thamnophis* opus,

which reads "To Roger Conant, my mentor and friend, who introduced me to the wonderful world of thamnophiine systematics and thereby changed the path of my professional life forever…" That Doug would have dedicated much of his publishing career to this genus is testament to the degree of meticulousness and perspicacity he brought to his work on a group of snakes whose initial revisor, A. G. Ruthven, described in his 1908 monograph as one that "has long stood in the minds of herpetologists as a synonym for chaos" (Rossman et al. 1996: 9). Though happy to tackle the problems within garter snake systematics, Doug first dabbled in studies in another vexing group, the Dusky Salamanders of the genus *Desmognathus*, naming his first new taxon *D. conanti*. Doug later averred that he was happy to have left systematics of that group to the molecular biologists. Aside from the salamander, Doug named three new subspecies, ten species, two genera, and one family of snakes.

Doug began his research into *Thamnophis* systematics while he was a doctoral student at UF. He chose to work on ribbon snakes (*T. proximus* and *T. sauritus*) for his dissertation, his monograph on which appeared in 1963. He continued to work on this subject until his masterwork appeared in 1996 and another piece of work on the Mexican snakes *T. scalaris* and *T. scaliger* in 1997, coauthored with G. Lara-Gongora. During those 34 years, Doug wrote some 20 papers on the members of the genus *Thamnophis*.

Although his name will be linked forever to the garter snakes, Doug was not a one-note snake systematist. We mentioned above that he also worked on other natricids in the New World, and he began to develop a long-standing interest in the dipsadid genus *Helicops*, a sort of ecological counterpart of the semiaquatic natricids found in South America. He wrote his first paper on a member of this genus in 1968 coauthored with Norman Scott; at the end of his life, he was working on a paper also dealing with this genus, which he was coauthoring with William Lamar.

Although a large amount of Doug's herpetological work dealt with snake systematics, he was also interested in other subjects in the field. The major evidence of such interest was his other book-length work, *The Amphibians and Reptiles of Louisiana*, coauthored with Harold Dundee, then of Tulane University. At the time, Doug and Harold were the two preeminent herpetologists in the state, so it was natural that they should band together to "work up" the herpetofauna of the state where they both lived and worked. This book won the 1990 Louisiana Literary Award for its two authors, a feat not often accomplished by authors of scientific works. Doug also worked and published on several groups of southeastern arachnids, and assisted other researchers by collecting invertebrates for them. A new species of crane fly that he collected on the screen door of his Baton Rouge home was named *Tipula rossmani* by George Byers, entomologist at the University of Kansas.

When Doug transitioned to LSU from Chapel Hill in 1963, one of his responsibilities was to attract students to the graduate program in zoology. It was in the spring of that year that he visited the campus of UF and enthused the senior author of this piece to become his first graduate student. Thus, in the fall of 1963, Wilson moved to Baton Rouge to begin what would become a five-year stint that led to his M.S. degree in 1965 and his Ph.D. in 1968. The work that Wilson undertook for his doctorate became exemplary of the sort of topics that Doug's subsequent doctoral students pursued, i.e., a taxonomic survey of a broadly-distributed species of snake occurring somewhere in the Western Hemisphere. During the period from 1967–1999, Doug oversaw the work of eight doctoral students, including Edmund D. Keiser (1967, *Oxybelis aeneus*), Larry David Wilson (1968, *Masticophis flagellum*), Kenneth L. Williams (1970, *Lampropeltis triangulum*), Richard M. Blaney (1971, *Lampropeltis getula*), Alexander Varkey (1973, North American natricine snake cranial myology), J. P. Richard Thomas (1976, Antillean *Typhlops*), Robin

Lawson (1985, thamnophine snake molecular systematics), and Jeff Boundy (1999, *Thamnophis sirtalis*). He also served as major professor for 17 M.S. students, including Janalee Caldwell, Donald Hahn, Darrel Frost, and Van Wallach.

Doug's initial pace in academia was busy. Within his first eight years at LSU, he graduated five Masters and three PhD students, applied for and received at least two grants, travelled internationally to collect specimens for his research, hosted an international symposium on snake systematics, and published 21 papers. His philosophies and techniques regarding science changed little during his career: usually a student selected a taxon or taxonomic group, and evaluated it for geographic variation and/or morphological adaptation. There were occasional projects involving anatomy and faunistic surveys, and even some genetics work. Typically, a graduate study could be completed with a dissection kit, stereomicroscope, and a typewriter. His first "molecular" study was a master's project by Gary Eberle that evaluated chromosomes in the cosmopolitan water snake genus *Natrix*. One result of that study was the recognition of North American water snakes as a distinct genus, *Nerodia*. That split offended Roger Conant so much that he turned his back on Doug for years, and it was only through the efforts of Jim Dixon's wife, Mary, that Conant reconciled himself with Doug. Robin Lawson's dissertation on New World natricine relationships evaluated allozymes, but that was the limit of Doug's involvement with molecular systematics. As the techniques for DNA extraction and sequencing advanced, and new phylogenies were constructed that were solely based on sequences, Doug became increasingly discouraged by the results. A typical complaint from 2011 reads "As I have said before, the molecular folks are self-admittedly trying to base their phylograms on 'selectively neutral mutations' and, in so doing, are deliberately assessing the effects of [genetic] drift and ignoring selection, which I would contend is the chief driving force of evolution since it is where the 'survival rubber hits the road' for individual species." Thus, up to his retirement, Doug's research continued to ponder adaptation through morphology, and in the antiquated fashion, he recorded raw data on specimen cards, wrote his manuscripts longhand with extraordinary penmanship, and sent these to the museum secretary to be typed for publication.

Doug Rossman retired from LSU in 1998 after 35 years of service. His retirement was the occasion for a gathering of many of his students and colleagues in Baton Rouge that brought people from as far away as Oklahoma, Florida, and New York. Although his longtime mentor was unable to travel from New Mexico, Roger Conant sent a letter of congratulations to Doug. The senior author of this piece served as a master of ceremonies for a meeting in the halls of the Louisiana State University Museum of Natural Science. He arranged with Rick Blaney to share the reading of this letter to Doug and the assembled body…but with a twist. When the time came, Larry called Rick to the podium and in front of Doug folded Conant's letter lengthwise and tore it in half. There was an audible gasp in the crowd, as Rick and Larry read the letter switching between left and right sides of the torn document. At the conclusion, Larry took both pieces and presented them to Doug with Conant's compliments. Doug was noticeably flabbergasted until later when he discovered that Rick and Larry had photocopied Conant's letter and used the photocopy during the reading. Thus, continued the longtime tradition of pulling jokes at the museum, often arranged by the two bad-boy students, Ed Keiser and Larry Wilson. For his part, Doug managed to suffer through these shenanigans with his characteristic good grace and aplomb.

At this point, Doug had been married to Sharon for eight years. Together, they decided on the direction of their lives, occasioning a move in 1999 almost directly north from Baton Rouge to Decorah, Iowa. Sharon and Doug decided to retire in Decorah for three reasons: one, because of the Scandinavian background; two, because of Luther College; and three, because of the beauty of the Decorah area (Tollenaar 2015). Decorah became Doug's home until his death 16 years later. Whereas this move might seem to be in jarring contrast to the life Doug spent as a university professor and researcher, he actually developed a range of interests in anthropology and the literary arts that marked him as a renaissance man among herpetologists. In fact, he acknowledged that in his college years, he was tempted to study anthropology rather than systematic biology.

The transition to avocational anthropology began with travels to southern Appalachia in the early 1970s, where Doug interacted with the Cherokee community. As a spiritual individual, he was particularly interested in their myths and legends, and eventually published a book on Cherokee mythic places and their spiritual significance. In the 1980s, he began a routine of spending summers in the upper Midwest, attending Nordic festivals, and story-telling and role-playing events. It was at one of these events that he met Sharon. Nearly full-time involvement in Norse culture enabled Doug to release his creativity in writing, and in his later years he published seven books on Norse Culture and of his own mythic Norse tales. These works were preceded in the early 1990s by four cassette tapes of Doug's alter ego, Dag, ormseeker and itinerant storyteller, explaining the origin of the Seven Worlds and his adventures therein. With characteristic subtle humor, Doug explained that *The Walker in Shadows* was the fourth and final book of the Dag trilogy. The previous book, *Way of the Elves*, contains a section that will convey, to anyone who knew Doug, his philosophy of one's earthly life—a window into his own soul. Doug was also a collector (and reader) of adventure and children's serials: Tarzan, Sherlock Holmes, Fu Manchu, the works of Frank Baum, and many others. He was co-founder of the Sax Rohmer Society, and at the time of his death was co-authoring an exhaustive biography of that writer.

Doug's gentle demeanor and sober assessment of science made him an exceptional instructor, advisor, and colleague. Whether at home or office, his door was always open, and he welcomed discussion of many topics, from fronto-nasal articulation of water snake skulls to the influence of animate spirits in the beliefs of early civilization. In his youth he learned to throw an atlatl, and in his last years learned to walk with two canes. Last year he and the junior author took a last walk together along a road across which some of his beloved natricines were travelling to their summertime haunts. Doug managed over a mile on the rutted track, his two canes keeping him upright long enough to see three snakes. Several months earlier, he wrote to Jeff that "I have reached a point where I can no longer dissect skulls out of pickled specimens….As you can imagine, this physical impediment—combined with my inability to walk on other than unimpeded level ground—has been hard to deal with emotionally. My career as a herpetologist did not end with my retirement in 1998 . . . but it is now a reality."

In the year that followed, Doug's mind was as keen as ever, but his ability to keep himself upright waned to a point that he needed Sharon's physical support to travel within the house. That tenuous situation came to an end when Doug collapsed, and Sharon was unable to raise him back to his feet. It was at that point that Doug consented to housing in a nursing home, but

his stay was short. After a few days there, his spirit unexpectedly departed.

Acknowledgments.—Our writing of this obituary for our friend and colleague would not have been possible without the assistance of a number of others, most especially Doug's widow Sharon, who graciously spoke at length with us during the first difficult days past her husband's death. We also were ably assisted by Janalee C. Caldwell, Kenneth L. Williams, Edmund D. Keiser, Richard M. Blaney, and Donald E. Hahn, who shared their reminiscences unstintingly about the influence Doug had on their lives.

Memories and Reflections: Phillip Andrew Cochran A Beloved Minnesota Biologist and Herpetologist (1956–2015)

There are few that have touched the lives of so many as Phillip Andrew Cochran. He was a selfless individual, whose academic prowess, candor, sincerity, and witty humor were coupled with extreme modesty that made him a true unsung hero.

Phil Cochran, Professor and Chairman, Department of Biology, Saint Mary's University, Winona, Minnesota, suffered a tragic event on 23 February 2015 that required his being airlifted from Winona Hospital to Gundersen Hospital, La Crosse, Wisconsin. To ease the minds of those concerned, and to insure that his students would not be deprived of a scheduled exam, he humorously sent a text message to his departmental administrative assistant while in transport reading, "I am on the way to my arraignment, hope to post bond tomorrow." She responded that she could proctor his exam, but would not post bond. Unfortunately, that was Phil's last text. After suffering an aortic aneurysm, Phil survived a complex surgery, but shortly thereafter a severe stroke proved unrelenting. Friends and family were ever-present at his side. It was hopeful Phil would recover. Unfortunately, it was not to be, and he passed away amidst the comfort of his family's love in the afternoon of 4 March 2015. A most touching memorial service was held in a packed Saint Mary's basketball gym on 14 March, where Phil regularly played noon round-ball games with his colleagues and friends. His oldest son, Joe (now a neurosurgeon), shared many moving memories on behalf of the family. There was not a dry eye in the field-house. Phil is survived by wife, Michelle; sons Joe, Andy, and Gus, and daughters Jesse and Jenny, and siblings Cathy, Chris, Randy, and Cindy.

Phil was born 13 September 1955. His dad, Andrew Gibbs Cochran, had been a pilot in the Air Force, an airline pilot, and then worked as an electrician when he and Phil's Mom, Mary Lou Bauer Cochran settled in Chicago around 1953. However, they soon moved to Bensenville, Illinois to raise their family. Phil's father passed away during his high school years after a ten-year battle with heart disease. Phil's character developed profoundly after the death of his father when the family (five siblings total) had a hard time making ends meet.

Early in life it was apparent that Phil would someday become a biologist as his brother, Chris, so clearly remembers those earlier years. "As a child, he loved to explore the swamps, ponds, wooded areas, and natural fields near our suburban home. He favored books about nature (the "How & Why" series were well-thumbed and dog-eared). As he learned about the world around us, he began to identify the various animals in our environment. I recall his triumphant return from an exploration of an area pond with jelly jars of water containing microscopic animals. He told me the Latin names, but to ease my understanding, gave them nicknames like Sams and Mergatroids. He knew which logs to turn to find salamanders, which pond would hold tadpoles, where the Starling would nest, what the names were of the various tree frogs and creeping critters. Many of these would be guests occupying jars in our bedroom."

Fig. 1. Phil Cochran with tubed Minnesota *Crotalus horridus*, his favored rattlesnake species, and a "nuisance" snake that he relocated to a protected area, August 2014.

"He learned to be a conservationist as a naturally felt responsibility to the nature that he loved. He led me, and our youngest

FIG. 3. A button symbolizing the memory of Phil designed by his beloved students.

brother, Randy, in keeping the environment clean. He led us (not exactly willingly), to scour the woods and remove trash. This became a great burden when, during the late 60s, large groups of 'hippies' invaded our wooded areas and clearings on most weekends and left enormous scatterings of cans, bottles, and debris. Phil would make us go in and drag it all out. I believe that this illustrates more than just his concern for the environment. He had a highly developed sense of conscience. He always did the right thing."

A trail of academic achievements began early in Phil's life. When it came time for Phil to consider what college he might attend, his wife Michelle fondly reflected about his first visit to Saint Mary's University in Winona, Minnesota in 1973 for an interview. He related how he had called from the Winona train station to the campus switchboard to tell them that he had arrived. He said the operator simply told him where to go stand, and stick out his thumb to hitch a ride to the campus. At the end of his visit, the admissions staff took him to lunch at Shorty's, and they drank a beer, before putting him on the train back to Chicago.

Without much hesitation, Phil decided to attend Saint Mary's, and he found himself enveloped in all of the things he loved, spending his college summers in Winona working on the Mississippi River. During his senior year in 1977 he met Michelle, a sophomore, and they married in January 1978. They lived in Roseville, Minnesota, while he was in graduate school at the University of Minnesota. To make financial ends meet, he worked as a night security guard, loaded bread trucks, and was a research / teaching assistant at the University. Michelle worked as a waitress, and their first child Joe was born during this time. Michelle recalls that "we were poor but very happy."

Phil completed a B.A. in Biology from Saint Mary's University, Winona, Minnesota in 1977. His undergraduate thesis concerned feeding ecology and growth in Spiny Softshell Turtles of the Upper Mississippi River Valley, and this was his initial academic effort in herpetology. He continued the pursuit of higher academics by completing an M.S. in Biology at the University of Minnesota in 1980. During this period he became involved with helping Dr. Jim Kitchell at the University of Wisconsin, Madison solve a complicated math problem concerning one of Jim's research publications. Not long thereafter, Phil was awarded a fellowship at the University of Wisconsin where Jim became his PhD advisor and a respected friend. For the next four years the Cochrans lived in a mobile home parked in Don's Mobile Manor (4 miles outside of Middleton, Wisconsin). His second son (Andy) and twin daughters (Jenny and Jesse) were born while living the trailer park life. Phil completed his PhD in Zoology in 1984, where he trained as an ichthyologist.

Phil accepted his first academic position with St. Norbert College, DePere, Wisconsin, as an Assistant Professor (1984–1991), and Associate Professor (1991–2000) with the Division of Natural Sciences. Aside from his teaching responsibilities he was always involved in research, setting and checking traps (fish, turtle, and any other creature that swam in) on the Fox River and the East and West Twin Rivers. Family outings were a favorite with picnic lunches along the river in Mishicot and fishing trips all around the area. Phil always had either his family or students in tow. When not accompanied by the whole family he often took along one of his older sons who enjoyed tagging along, especially with college students. During the family time in DePere his wife said, "he kicked me back into college, encouraged and gently pushed me to continue with art studies. Under his loving care I earned degrees in Art, Art Education, and Adaptive Education. This all formed a basis for my having a job that would sustain me, as he had always told me that I needed to be able to earn a living in case he was not around. He encouraged all the family to do what they love."

Although Phil had a wonderful career at St. Norbert, in 2000 a job opened at Saint Mary's University in the Biology Department that seemed like it was designed with him in mind. It was not long after Phil's return to Saint Mary's that he became headlong involved with Minnesota's keystone snake species, the Timber Rattlesnake, *Crotalus horridus*. His interest in the conservation and natural history of this species in the Upper Mississippi River Valley was of the most genuine and sincere in every aspect. He

responded to calls when rattlesnakes were found in yards and school areas, and would relocate the snakes to a secure site. He inspired many students in the study of the biology, natural history, genetics, and ecology and conservation of the Timber Rattlesnake in the region. Along with his newfound interest in Timber Rattlesnakes he continued his studies of the fishes and turtles of the Upper Mississippi, working with sturgeon (*Scaphirhynchus albus* and *S. platorynchus*), paddlefish (*Polyodon spathula*), and his beloved lampreys (*Ichthyomyzon unicuspis,* and multiple other lamprey genera and species). Phil worked in concert with academics from other institutions, the state Department of Natural Resources, and conservation groups to improve the conservation and scientific study of all things natural. His academic, motivational, and inspirational talents with students soon led to his becoming Chairman of the Department of Biology in 2004. Additionally, he served as Acting Associate Dean of Mathematics and Sciences, 2011–2012.

Phil's herpetological and ichthyological studies ranged across international borders, extending into Mexico, and Central and South America. However, during the past decade his keen interest in all aspects of Timber Rattlesnake biology was reflected in a series of publications (Cochran 2008; 2010; 2014a, b, c; Cochran and Riebel 2014; McLaughlin et al. 2015). Phil hosted the first Timber Rattlesnake Symposium in Minnesota at Saint Mary's University, in Winona, 24 September 2005, and published the proceedings (Keyler and Cochran 2005). Collectively, his publications in journals, newsletters, books, briefs, and bulletins number in the hundreds, and he was an internationally recognized biologist. Despite these and many more contributions he made to us all, Phil never boasted of his achievements, and would always generously share the credit of his efforts.

Significantly, in addition to his academic and scholarly penmanship, Professor Cochran enriched the lives of his students. He has undoubtedly motivated hundreds of biology students to further their scientific knowledge, and use it to conserve our natural world and expand horizons in multiple scientific fields. He touched the minds and hearts of more students than he ever realized.

We have lost a Champion to herpetological education, a Champion mentor to future biologists and herpetologists, a Champion to conservation of our natural world, a Champion for the Timber Rattlesnake, and a Champion to humanity and his family. The fish and turtles of Ole' Man River, the Father of Rivers, and the snakes and other creatures of the Blufflands of the Mighty Mississippi River Valley will all remember his spirit. And, when the winds whisper through the Valley and up over the Blufflands it will carry Phil's spirit. The people of the Upper Mississippi River Valley whose lives he touched will carry on in his footsteps. The path this humble human being started will be forever ongoing through the lives of all that knew him. I will miss having a Rush River or Snake Hollow barley pop (as he referred to a good beer) with my colleague and friend after a day of climbing the Mississippi River bluffs in search of *Crotalus horridus*, but know that he is in the field with us always.

Gans Fund Announces Student Grants to Three Conferences for 2016

The Carl Gans Collections and Charitable Fund is pleased to announce that it will support attendance awards to students—both graduate and undergraduate, but not postdoctoral—who are attending any of the following three conferences in 2016:

International Society of Vertebrate Morphology (ICVM) June 29 – July 3 in Washington, DC

Joint Annual meeting of ASIH, HL, and SSAR (JMIH) July 6 – 10 in New Orleans, Louisiana

8th World Congress of Herpetology (WCH) August 15 – 21 Hangzhou, China

The awards are open to all students regardless of nationality who are eligible to register at the specific conference. **The deadline for receipt of applications is March 15, 2016.**

To be eligible, applicants (1) must certify their student status with a separate message from their professor; (2) must list the herpetological society or societies to which they belong; (3) must be intending to present a paper (oral or poster) at the meeting; and (4) the paper's subject area must be within the broad spectrum of research conducted by Professor Gans on the biology of amphibians and reptiles (especially morphology, systematics, faunistics, behavior, physiology, and evolution). Applicants must provide a paragraph or abstract (no more than 300 words) describing the work to be presented at the meeting, to enable the selection process. Award announcements will be made around April 15, 2016, allowing all applicants to know their status before meeting registrations begin.

Selections will be made by the Gans Fund, on the recommendation of its Scientific Advisory Board. The Board consists of: Kraig Adler, Cornell University (USA), Aaron Bauer, Villanova University (USA), Amos Bouskila, Ben Gurion University (Israel), Herbert Rosenberg, University of Calgary (Canada), Linda Trueb, University of Kansas (USA).

All applications must be made at: http://www.carlgans.org (click on "Grants" in top menu bar). For additional information on these and other grant opportunities, sign up for our free email list on our web site.

SSAR TO ESTABLISH A NEW ENDOWMENT

The Dr. Margarita Metallinou Postdoctoral Travel Award

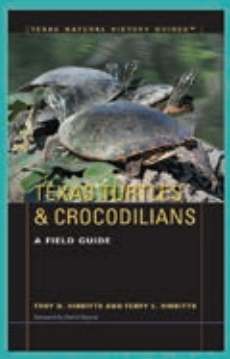
DR. MARGARITA METALLINOU was a talented evolutionary biologist and herpetologist whose career was just beginning to blossom. She completed her undergraduate studies at the University of Athens in Greece, an MSc at the University of Barcelona in Spain, and by the age of 28 a Ph.D. at the Institute of Evolutionary Biology at Barcelona where she studied the systematics and biogeography of North African and Arabian Short-fingered Geckos (*Stenodactylus*) and Fan-fingered Geckos (*Ptyodactylus*) under the direction of Dr. Salvador Carranza. She participated in three expeditions to North Africa and Arabia. During her time in Barcelona she proved to be a brilliant and enthusiastic student who captivated instructors and fellow students with her thoughtful questions, her eagerness to learn, and her great spirit. In August 2014, Margarita moved to the United States for a postdoctoral position at Villanova University with Profs. Aaron Bauer and Todd Jackman. A gifted and vivacious leader, within weeks of settling in she began to rapidly transform the research group. Within the lab she instituted novel protocols and mentored graduate students as they developed their individual research projects, while outside of the lab she organized lab meetings and led classroom discussions, using her experience to provide unique insights. Margarita's cheerful demeanor and spirited personality not only drew everyone around her closer, but also created a friendly and pleasant working environment.

Tragically, Margarita's life was cut short in a wildlife accident while conducting fieldwork in Zambia, southern Africa, in July of 2015. She had been scheduled to present her latest results at the SSAR meeting later that month at the University of Kansas. The suddenness of her loss has shaken the entire scientific community who not only lost a promising and gifted researcher, but also a brilliant and vibrant role-model for aspiring female scientists. **To commemorate her legacy, SSAR wishes to establish a Postdoctoral Travel Award endowment for one or more persons to attend the Society's annual meetings**. These annual awards will honor in perpetuity Margarita's dedication and passion for science, her tenacity, her boundless energy, her ability to help everyone around her, and her determination to enjoy life and follow her dreams. Donations to support this endowment can be made to SSAR (see below).

TO DONATE TO SSAR: Donations by credit card may be made directly to the foundation that holds the society's endowments: Truman Heartland Community Foundation (THCF) at www.thcf.org. *This is a completely secure site.* Click "Donate Now" near the upper left corner. On the next page, find "Nonprofit Funds" near the bottom and scroll down to "SSAR" and the "Metallinou Postdoctoral Fellow Endowment." Fill in the blanks on the next page, click "Process" at the bottom, and you will get a printed receipt (for IRS purposes if in the USA). If you prefer, a personal check can be made out to "SSAR—Postdoctoral Fellowship" and sent to the Society's Treasurer: Dr. Ann Paterson, PO Box 3692, 60 W. Fulbright Ave., Walnut Ridge, AR 72476, USA. Overseas donors may use the THCF site or may seek additional advice for payment by emailing Dr. Paterson at apaterson@wbcoll.edu.

Texas Lizards
A Field Guide

BY TROY D. HIBBITTS AND TOBY J. HIBBITTS
FOREWORD BY LAURIE J. VITT



In this extensively illustrated field guide, two of the state's most knowledgeable herpetologists present the first complete identification guide to all fifty-one native and established exotic lizard species that live in Texas.

RELEASE DATE | MAY 2015

351 pages, 229 color photos, 53 maps
ISBN: 978-0-292-75934-3
$24.95 paperback | $24.95 e-book

Texas Turtles & Crocodilians
A Field Guide

BY TROY D. HIBBITTS AND TOBY J. HIBBITTS
FOREWORD BY DAVID HAYNES

The first complete identification guide to all the state's turtles and to its single alligator. It offers detailed species accounts, range maps, and excellent color photographs to aid in field identification.

AVAILABLE | JANUARY 2016

264 pages, 117 color photos, 36 maps
ISBN: 978-0-292-75934-3
$24.95 paperback | $24.95 e-book

UNIVERSITY OF TEXAS PRESS

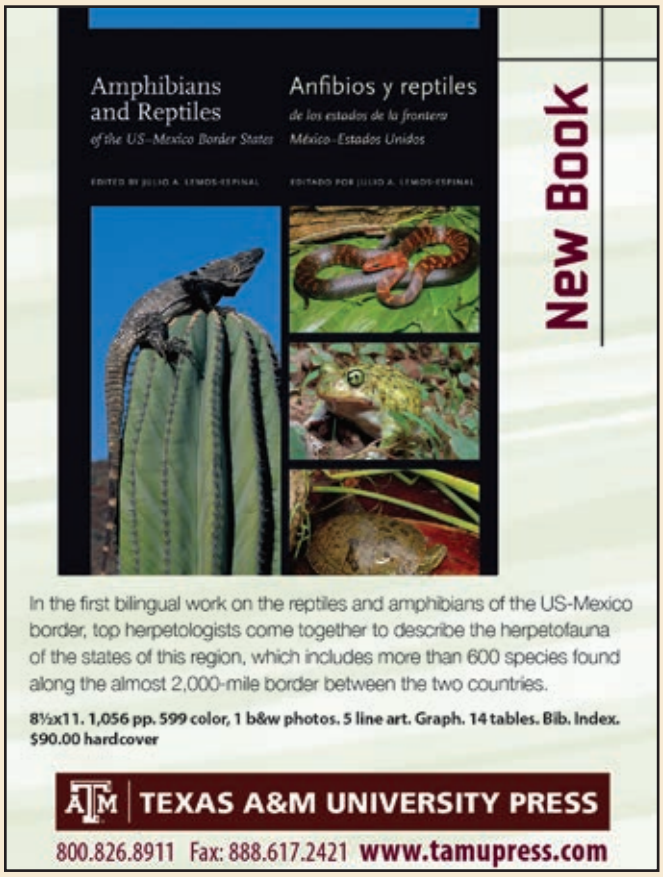
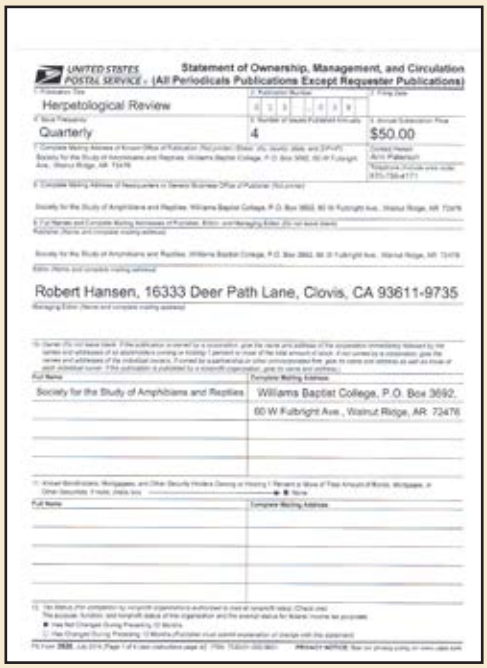
NEW EDITION

Snakes
OF THE SOUTHEAST
BY WHIT GIBBONS AND MIKE DORCAS

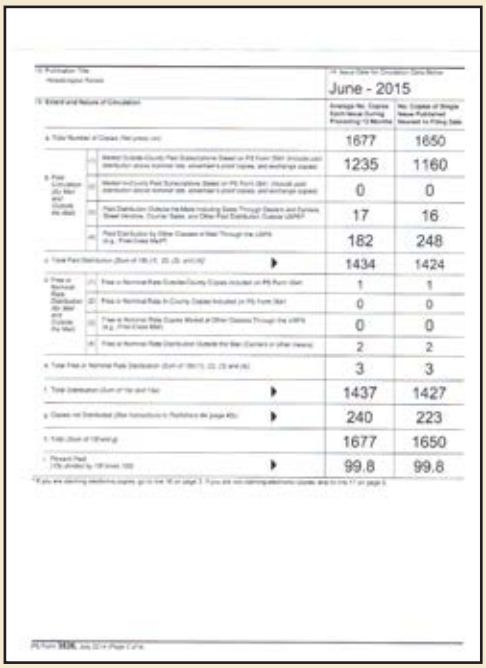
SNAKES OF THE SOUTHEAST
Revised Edition
Whit Gibbons and Mike Dorcas
PAPER, $28.95 | 978-0-8203-4901-5



A Wormsloe Foundation nature book



FEATURES:



- Conservation-oriented approach
- Over 300 color photographs, including many new images for this edition
- New distribution maps for 53 species of snakes
- New accounts of invasive snakes of the Southeast
- Clear descriptions of each species, including differences in the appearance of young and mature snakes
- Size charts, key identifiers (scales, body shape, patterns, and color), descriptions of habitat, behavior and activity, food and feeding, reproduction, predators and defense, and conservation

INFORMATION FOR CONTRIBUTORS

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes concerning the study of amphibians and reptiles, as well as book reviews, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (for information, please refer to: http://www.ssarherps.org/pages/JHinstr.php). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

http://ssarherps.org/publications/journals/herpetological-review/

REPRINTS AND PAGE PROOFS

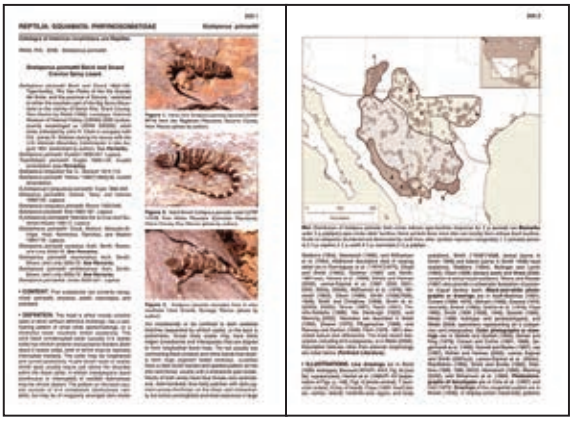
Page proofs are sent electronically to authors of all articles, book reviews, and obituaries, but are not prepared for natural history, geographic distribution, or herpetoculture notes. Proofs are sent as pdf files approximately 2–4 weeks prior to publication. High resolution electronic (pdf) reprints of notes, articles, book reviews, and obituaries are provided at no charge to the primary/corresponding author as a benefit of SSAR membership. Reprint files will normally be sent prior to the issue mailing date from the printer. Authors who are not current SSAR members may purchase pdf reprints from the SSAR Publications Office.

ADVERTISING

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pages/HRinfo.php).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at the Department of Natural Sciences, Williams Baptist College, P.O. Box 3692, Walnut Ridge, AR 72476, USA. Periodicals postage paid at Walnut Ridge, AR 72476 and at additional mailing offices.

All rights reserved. No part of this periodical may be reproduced without written permission of the Editor, except that authors and their agents are permitted to reproduce and distribute their own articles and notes.



POSTMASTER: Send address changes to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158. **MISSING OR DAMAGED ISSUE?** Please notify Breck Bartholomew, SSAR Publications Secretary (e-mail: ssar@herplit.com) for a replacement.

SSAR PUBLICATIONS

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: http://www.ssarbooks.com/.

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

The *Catalogue* consists of individual accounts of species and genera prepared by specialists, including synonymy, definition, distribution map, and comprehensive list of literature for each taxon. The accounts cover amphibians and reptiles of the entire Western Hemisphere. As of 2014, SSAR is making all CAAR accounts OPEN ACCESS as a service to the herpetological community. To access individual accounts, visit http://www.ssarcaar.com.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its bulletin, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

To join SSAR or to renew your membership, please visit the secure online ZenScientist website via this link:

Helminths of Night Lizards in the Genus *Xantusia* (Squamata: Xantusiidae) and the Effects of Host Ecology

The 34 living species of the Xantusiidae are arrayed in three genera distributed from the southwestern United States to Panama with a single species in Cuba (Noonan et al. 2013). The northernmost genus, *Xantusia* (Night Lizards), contains 14 named species with populations scattered from southern Utah to Durango and Zacatecas, Mexico (Bezy and Flores Villela 1999; Sinclair et al. 2004; Bezy et al. 2008); plus two genetically isolated lineages that remain to be formally described (Leavitt et al. 2007).

Night Lizards (*Xantusia*) are secretive, philopatric lizards that may be found under the same cover throughout life (Zweifel and Lowe 1966; Mautz 1993; Davis et al. 2011) but occasionally have been observed active abroad (Lee 1975; Fellers and Drost 1991). The species are habitat specialists, living primarily in rock crevices, under rocks, or in decaying yuccas, agaves, and other plants (Bezy 1989). As a result of these microhabitat restrictions they may be exposed to fewer sources of parasites than most other lizards.

Gastrointestinal parasites have been reported previously in four species of *Xantusia*: Bolsón Night Lizard, *X. bolsonae*; Granite Night Lizard, *X. henshawi*; Island Night Lizard, *X. riversiana*; and Desert Night Lizard, *X. vigilis* (Lucker 1951; Brattstrom 1952; Read and Amrein 1952; Telford 1970; Goldberg 1985; Goldberg et al. 1993). In general, helminth species appear to have a high level of endemism in xantusiids (Goldberg et al. 1993). We here report the helminths of five additional species with small geographic ranges and discuss the relationship of the lizards' habitat and ecology to their parasite communities.

Two species live primarily in yuccas and agaves: *Xantusia wigginsi* (Wiggins' Night Lizard) in the Sonoran Desert of Baja California, Mexico, and extreme southern California, and *X. extorris* (Durango Night Lizard) in the southern Chihuahuan Desert of Durango and Zacatecas, Mexico; three occur primarily in rock crevices: *X. sierrae* (Sierra Night Lizard) in the western foothills of the Greenhorn Mts. of California, *X. arizonae* (Arizona Night Lizard) and *X. bezyi* (Bezy's Night Lizard) in the mountains of central Arizona (Webb 1965; Bezy et al. 2008; Sinclair et al. 2004; Noonan et al. 2013).

Materials and methods.—A sample of 86 xantusiid lizards consisting of nine *Xantusia arizonae* (mean snout–vent length, SVL = 51.4 mm ± 4.7 SD, range = 42–56 mm), 12 *X. bezyi* (mean SVL = 52.1 ± 3.3 SD, range = 47–60 mm), 24 *X. extorris* (mean SVL = 35.5 mm ± 3.0 SD, range = 30–42 mm), 21 *X. sierrae,* (mean SVL 43.8 mm ± 4.4 SD, range = 36–51 mm), 20 *X. wigginsi* (mean SVL = 36.1 mm ± 3.1 SD, range = 31–43 mm) were borrowed from the herpetology collections of the Natural History Museum of Los Angeles County (LACM), Los Angeles, USA and the University of Arizona Museum of Natural History (UAZ), Tucson, Arizona, USA, and examined for helminths (Appendix 1).

The digestive tract was removed and the contents of the esophagus, stomach, small and large intestines were examined under a dissecting microscope. Cestodes were regressively stained in hematoxylin, dehydrated in an ascending series of alcohols, cleared in xylol, mounted in Canada balsam, cover slipped and studied under a compound microscope. Nematodes were placed on a microscope slide, cleared in lactophenol, cover slipped and studied under a compound microscope. Parasite terminology is according to Bush et al. (1997).

Results.—Found were one species of Cestoda, *Oochoristica bezyi* Bursey and Goldberg, 1992 and three species of Nematoda,

*References: 1. Goldberg 1985; 2. This study; 3. Goldberg et al. 1993; 4. Read and Amrein, 1952; 5. Telford 1970; 6. Lucker 1951.

Thubunaea iguanae Telford, 1965, *Parapharyngodon californiensis* (Read and Amrein, 1952), and *Physaloptera* sp. (Tables 1–2). *Parapharyngodon californiensis* had the highest prevalence (infected individuals/number examined × 100) and *Oochoristica bezyi* had the highest mean intensity (mean number of helminths per infected lizard) (Table 1).

Voucher helminths were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland, USA as: *Xantusia arizonae*: *Oochoristica bezyi* (USNPC 108200); *Parapharyngodon californiensis* (USNPC 108201); *Physaloptera* sp. (larva) (USNPC 108202); *Xantusia bezyi*: *Oochoristica bezyi* (USNPC 108203); *Parapharyngodon californiensis* (USNPC 108204); *Xantusia sierrae*: *Oochoristica bezyi* (USNPC 108205), *Parapharyngodon californiensis* (USNPC 108206); *Xantusia wigginsi*: *Thubunaea iguanae* (USNPC 108207). All helminths are new host records for *X. arizonae, X. bezyi, X. sierrae,* and *X. wigginsi*, respectively.

Discussion.—*Oochoristica bezyi* was described from *Xantusia vigilis* from the southern Mojave Desert in Los Angeles and San Bernardino counties, California, by Bursey and Goldberg (1992). It also has been reported from *X. henshawi* (Goldberg et al. 1993). Although the life cycle of *O. bezyi* has not been studied, Conn (1985) found that tenebrionid beetles served as intermediate hosts for the congener *O. anolis*. *Parapharyngodon californiensis* is, to date, restricted to xantusiid lizards (Baker 1987; Goldberg et al. 1993). Like other oxyurids (Anderson 2000), *P. californiensis* has a direct life cycle with no intermediate host. Infection presumably occurs by lizards ingesting eggs from infected substrate during feeding. The physalopterid, *Thubunaea iguanae* presumably utilizes an intermediate host (Anderson 2000).

Considering the ecological distribution of the xantusiid hosts, the high prevalences of *P. californiensis* in rock crevice species *X. arizonae, X. bezyi, X. bolsonae, X. henshawi,* and *X. sierrae* (67%, 58%, 50%, 28% 57%, respectively) is noteworthy and contrasts sharply with that in *Xantusia* species living in yuccas and agaves, i.e., *X. vigilis, X. wigginsi,* and *X. extorris* (1%, 0%, 0%, respectively). The reasons for high prevalences of *P. californiensis* in rock crevice *Xantusia* are speculative, but the

rock crevices may allow accumulations of moist feces promoting excellent opportunities for repeated infections. The dryer, more complex microhabitats of yucca-dwelling species may promote a sporadic infection rate. In *Sceloporus jarrovii* (Yarrow's Spiny Lizard), a phrynosomatid species that utilizes rock crevices, Goldberg and Bursey (1992) found that 74% of neonates between one day and two weeks of age were infected with eggs or larvae of the oxyurid nematode *Spauligodon giganticus* which has a direct life cycle. Infection of *Sceloporus jarrovii* by *Spauligodon giganticus* likely is facilitated by the substrate licking behavior of *S. jarrovii* (DeFazio et al. 1977), which promotes ingestion of parasite eggs from the soil.

Oochoristica bezyi was present in all rock crevice species (Table 2) except *X. bolsonae*. In yucca dwellers it was present in *X. vigilis,* but absent in *X. wigginsi* and *X. extorris.* This might reflect sample size or conceivably that the range of *O. bezyi* and its intermediate tenebrionid host do not extend south to either Baja California or Durango, Mexico. The rock crevice species *X. arizonae, X. henshawi* (Brattstrom 1952), and presumably *X. bezyi* and *X. sierrae* include coleopterans (supposed intermediate hosts for *Oochoristica*) in their diets, which would facilitate cestode infection.

Turning to an island endemic that lives under rocks, in a moist maritime climate, *X. riversiana,* besides harboring a unique species of cestode, *O. islandensis* Bursey and Goldberg, 1992, it is host to four unique species of nematodes, with direct life cycles, *Alaeuris clementensis* (Telford, 1965), *A. riversianae* (Telford, 1965), *Parapharyngodon pseudothaparius* (Telford, 1965) and *P. xantusi* (Lucker, 1951) (Lucker 1951; Telford 1970; Goldberg et al. 1993). Fellers and Drost (1991) found that on Santa Barbara Island, California 29% of the fecal samples of *X. riversiana* harbored oxyurid nematodes. We have observed the accumulation of fecal piles in one corner of the space under rocks inhabited by *X. riversiana* (Fig. 1) and this likely facilitates infection by the four oxyurid (direct life cycle) nematodes unique to *X. riversiana*. This may help explain why *P. californiensis*, which is common in rock crevice xantusiids from Arizona and California, was absent from *X. riversiana* under rocks on San Clemente Island, suggesting the use of defecatoria and the moist maritime climate may favor survival of oxyurid species other than *P. californiensis*.

Acknowledgments.—We thank Greg Pauly (LACM) and George Bradley (UAZ) for permission to examine xantusiid lizards and Jeanette Arreola for assistance with dissections.

New Northern Distribution Records for Pattern Classes A, B, and D of *Aspidoscelis neotesselata* (Colorado Checkered Whiptail) in Colorado, and Biogeographic Sources of Northern Colonists

Aspidoscelis neotesselata (Colorado Checkered Whiptail) originated from a hybridization event between individuals of *A. tesselata* (Common Checkered Whiptail) and *A. sexlineata viridis* (Prairie Racerunner) (Parker and Selander 1976; Dessauer and Cole 1989; Walker et al. 1995; Taylor et al. 2015). *Aspidoscelis neotesselata* inherited its parthenogenetic mode of reproduction from *A. tesselata*, and embryogenesis in both species is initiated and completed independently of spermatozoa. Therefore, a local group of *A. neotesselata* females lacks the genetic cohesion of a local population of a sexually reproducing species, and clonal divergence—a consequence of random mutation—is the principal mode of evolution. Based on the mother-daughter pattern of descent in obligate parthenogens, with evolution expressing itself as clonal divergence, local groups of related parthenogenetic females are more appropriately referred to as "arrays" ("tokogenetic arrays" of Frost and Hillis 1990) rather than "populations."

Color pattern differences among arrays of *A. neotesselata* illustrate that clonal inheritance has not prevented postorigin evolution (Taylor et al. 2015). Although ontogenetic and individual variation add to the challenge of discerning discrete

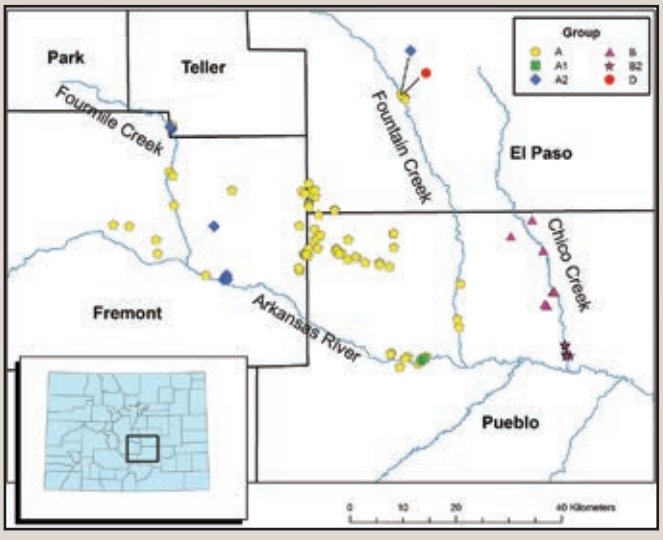

FIG. 1. Selected localities showing the geographic distributions of pattern classes A, B, and D of *Aspidoscelis neotesselata*, primarily north of the Arkansas River in El Paso, Fremont, Pueblo, and Teller counties, Colorado. Symbols identify localities detailed in Appendices 2 and 3. Yellow pentagons = pattern class A lacking statistical confirmation of A1 or A2 group; green squares = group A1 of pattern class A; blue diamonds = group A2 of pattern class A; magenta triangles = pattern class B lacking statistical confirmation of B1 or B2 group; magenta stars = group B2 of pattern class B; red circle = pattern class D.

FIG. 2. Photograph of an individual of *Aspidoscelis neotesselata* of pattern class B (with a partially regenerated tail) taken on 27 June 2014 at Chico Basin Ranch by William Maynard—the northernmost record of *A. neotesselata* B for Pueblo County, Colorado. This individual can be identified as pattern class B by the prominent longitudinal mid-vertebral line and transverse white bars crossing the lower lateral dark field.

FIG. 3. Individuals of *Aspidoscelis neotesselata* at Fountain Creek Nature Center and Fountain Creek Regional Park (Appendix 3). This area supports the northernmost self-sustaining array of *A. neotesselata* that has been discovered in Colorado. A) An individual of pattern class A, photographed by Don Erickson on 13 July 2012 at FCNC, El Paso Co., Colorado. B) A juvenile individual of *A. neotesselata* hatched in 2014, photographed by William Maynard on 27 October 2014 at the north end of Rice's Pond, FCNC. Photographs are not at same scale.

groups within this variation, specific color pattern attributes have been used to identify four color-pattern classes. These are designated by capital letters: A and B (Zweifel 1965), C (Walker et. al. 1997), and D (Walker et al. 2012).

Histocompatibility among color pattern classes (Walker et al. 2012; J. E. Cordes and J. M. Walker, unpubl.) indicates that *A. neotesselata* originated from a single parthenogenetic hybrid, thereby nullifying a hypothesis that color pattern classes A and B were derived from different hybridization events (Densmore et al. 1989). Additional morphological groups, designated as A1, A2, B1, and B2 within pattern classes A and B, were revealed by multivariate statistical analyses of meristic characters (Taylor et al. 2015). Because pattern classes A, B, C, and D are typically allopatric, as are groups A1, A2, B1, and B2, pattern classes are useful for depicting fine-scale geographic distributions, and pattern class groups have value in identifying genealogical sources of disjunct arrays.

This project was a collaborative effort to clarify the distribution of *A. neotesselata* north of the Arkansas River in southeastern Colorado. New localities include those that add El Paso and Teller counties to the four-county distribution (Fremont, Las Animas, Otero, and Pueblo) previously known to define the general range of *A. neotesselata* in Colorado. We also report an elevation record for *A. neotesselata* in Teller County that substantiates one reported from Fremont County (Banta and Kimmel 1965). Finally, we identify the likely biogeographical sources of the northern arrays of pattern classes A and D that now define the northern boundary of the species' range in Colorado.

Methods and materials.—Only two whiptail lizards, *A. neotesselata* and *A. sexlineata viridis*, are present in the study area, and these species have distinctive color patterns and coloration, making species misidentification unlikely (Hammerson 1999, plates 8.55 and 8.56). We documented new distribution records of *A. neotesselata* by voucher specimens, photographs, and reliable observations. We obtained direct GPS coordinates for most localities (UTM coordinates based on GPS datum WGS84). In a few instances, the location was estimated by comparing the observation location with satellite images available on Google Earth©. For published localities, we used associated information to map estimated localities. We determined elevation for each set of coordinates by mapping them in National Geographic TOPO! © (Version 4.5.0) software and obtaining the elevation from the Quad level map (USGS 1 arc-second National Elevation Dataset, 1 meter vertical precision).

We used seven meristic characters in the multivariate analyses (Appendix 1; Table 2). The L-breaks character is subject to ontogenetic development. Therefore, we used linear regression to check reference samples for a relationship between L-breaks and snout–vent length (SVL). This relationship was

TABLE 1. Descriptive statistics for samples of *Aspidoscelis neotesselata* from southeastern Colorado. PNC A1 = pattern class A from Pueblo Nature Center; Fremont A2 = pattern class A from Fremont County; LJ D = pattern class D from La Junta (Appendix 2). Means ± SE and range limits are shown. Means sharing the same letter (a, b, c) are not significantly different at $\alpha = 0.05$. Group assignments of voucher specimens by CVA are shown below specimen numbers. FCNC = Fountain Creek Nature Center, El Paso County.

found in sample A2 and removed by using only specimens > 65 mm SVL in the analyses. We used the seven univariate characters in a principal components analysis (PCA) of a pooled sample of voucher and reference specimens to produce a set of uncorrelated principal components; these were used as characters in a canonical variate analysis (CVA) for definitive comparisons (Jombart et al. 2010). Because all characters were measured on the same scale (discrete counts of scales and femoral pores), we used a variance/covariance matrix to obtain coefficients used to compute principal component scores. A variance/covariance matrix retains the relative variances of original characters, so that characters with larger variances are given greater weight in developing the principal components (Neff and Marcus, 1980). We used reference samples of A1, A2 and D as a priori (preidentified) groups (Appendix 2), and stepwise selection of principal components to include in the CVA (*F*-to-enter probabilities < 0.05 that did not exceed 0.06 when other components were added to the model). The six voucher specimens from Fountain Creek Nature Center (FCNC), El Paso County, and Shelf Road, Teller County, were included in the CVA as unassigned individuals for classification to the reference sample each most closely resembled. We used Mahalanobis D^2 distance as a resemblance index (smaller D^2 values = greater resemblance and higher probability of correct classification of vouchers). Mahalanobis D^2 distances are sensitive to multivariate outliers (Tabachnick and Fidell, 2013). Therefore, we checked each reference sample for multivariate outliers by evaluating D^2 distances from each specimen to the centroid of the remaining cases. Specimens would be identified as outliers from a standard table of critical values for Chi Square; i.e., those with D^2 values exceeding a critical Chi-square value at $P = 0.001$, and degrees of freedom defined by the number of characters (principal components) included in the CVA model (Tabachnick and Fidell, 2013). We used SPSS© and NCSS© software for statistical routines, tests, and scatterplot construction.

Results.—Three key pieces of evidence formed the foundation of this study. First, Dick Roth discovered *A. neotesselata* in Teller County on 16 July 2004 (Fig. 1; Appendix 3) and documented a new elevation record of 2138 m for this species (UTM 13S 480729E, 4279916N). We augmented this Teller County record with voucher specimens collected on 21 August 2014, approximately 0.3 km S of Dick Roth's 2004 observation location (Appendix 3). All were representatives of pattern class A (Fig. 4A: a–c).

Second, a photograph taken by William Maynard on 27 June 2014 at Chico Basin Ranch (CBR), Pueblo County (Fig. 2; Appendix 3), documented a new northern record for pattern class B of *A. neotesselata*. Latitudinally, the photographic location (UTM 13S 548568E, 4261673N) is approximately 24 km N of the previous northernmost record for pattern class B (UTM 13S 554644E,

TABLE 2. Loadings: correlations between seven meristic characters and principal components 1, 2, and 4 and between five principal components (selected for inclusion in the CVA model) and canonical variates 1 and 2: multivariate statistical analyses of *Aspidoscelis neotesselata* pattern classes A and D from southeastern Colorado.

4238113N) at Pueblo Chemical Depot (PCD), Pueblo County (Taylor et al. 2006a). We made two unsuccessful attempts in August 2014 to collect a voucher specimen from the CBR location.

Third, a photograph taken at FCNC by Don Erickson on 13 July 2012 (Fig. 3A) and posted on http://www.donerickson.com/reptiles/reptiles.html provided the first evidence of *A. neotesselata* in El Paso County. Significantly, this photograph and voucher specimens collected from the photographic location (UTM 13S 524574E, 4284921N) document a new northernmost record for *A. neotesselata* in its natural range. A young individual, photographed on 27 October 2014 by William Maynard (Fig. 3B), indicates that *A. neotesselata* had reproduced successfully at FCNC in 2014. We collected three voucher specimens of *A. neotesselata* from FCNC (Appendix 3), two of pattern class A (Fig. 4B: d, e), and one of pattern class D (Fig. 4B: f). The latter was unexpected because the distribution of pattern class D is centered on a small area associated with railroad yards in northeast La Junta, Otero County, approximately 125 straight-line km SE of FCNC (Walker et al. 2012; Taylor et al., *in press*). We determined the morphological affiliations of voucher specimens from FCNC and Teller County by a CVA in which reference samples of A1, A2, and D were used as a priori groups (Appendix 2), and the six voucher specimens were included as unassigned for classification to group. Two outliers in the PNC sample and four specimens with SVL < 65 mm in the Fremont County sample were excluded from the definitive multivariate analyses. Reference samples differed significantly for different combinations of univariate characters (Appendix 1). Reference samples A1 and A2 differed in SDL, SPV, and FP, whereas the reference sample of pattern class D differed from A1 in LSG, GAB, and FP, and from A2 in LSG, SDL, GAB, and SPV (Table 1). The CVA model (Table 2) classified 68 of the 75 reference specimens (90.7%) to correct samples of origin. Reference sample PNC A1 had 4 of 27 specimens misclassified as Fremont County A2, and reference sample Fremont A2 had 3 of 30 specimens misclassified: 2 to PNC A1 and 1 to LJD D. None of the individuals in the LJD D reference sample was misclassified. This overall high level of classification success was reflected by the significant differences in CV1 among the three reference samples (Table 1).

Each of the three voucher specimens from Teller County was assigned to reference sample A2 by the CVA (probabilities of 0.990 for HLT 399; 0.957 for HLT 400; and 0.937 for HLT 401). The two voucher specimens of pattern class A from FCNC were also assigned to reference sample A2 (probabilities of 0.969 for HLT 396 and 0.987 for HLT 397). Our identification of specimen HLT 398 as pattern class D was supported by its classification to the reference sample of pattern class D from La Junta (P = 0.963). The probability that HLT 398 actually represented A2, the group to which the other two FCNC vouchers were classified, was only 0.021. These robust classifications of voucher specimens are shown graphically by their positions in A2 and D clusters of canonical variate scores (Fig. 5). Although CVA classified FCNC and Teller County voucher specimens of pattern class A to group A2, vouchers from these two localities are distinctly different in GAB scores. All FCNC vouchers (pattern class A as well as pattern class D) most closely resembled the reference sample of pattern class D in GAB (Table 1).

Discussion.—Our locality records (Fig. 1; Appendices 2 and 3) extend the known distribution of *A. neotesselata* into Teller and El Paso counties, verify a previously reported elevation record, and establish a new northern range limit for *A. neotesselata* in Colorado. These new county records are of particular significance because they provide information regarding the ecological amplitude and the potential for range expansion in *A. neotesselata*.

The range of *A. neotesselata* extends approximately 173 km WNW beyond the range of *A. tesselata* in Colorado (Taylor et al. 2006b). Therefore, because triploid *A. neotesselata* inherited a diploid genome from *A. tesselata* and a haploid genome from *A. sexlineata viridis* (Neaves 1969; Parker and Selander 1976; Taylor et al. 2015), the greater ecological breadth of *A. neotesselata* may be related to the genome inherited from *A. sexlineata* (Taylor et al. 2006b). A natural experiment based on elevation records for the three species supports this hypothesis. We have not encountered *A. tesselata* above 1507 m in Colorado. Specimens of both *A. tesselata* and *A. neotesselata* were collected at this elevation by HLT on 11 June 2005 from a juniper (*Sabina monosperma*) woodland north of Lockwood Canyon and west of the Sharp Ranch road, U.S. Army Pinyon Canyon Maneuver Site, Las Animas County (UTM 13S 601962E, 4151131N). Other prominent plants at this site were skunkbush sumac (*Rhus* sp.), snakeweed (*Gutierrezia* sp.), and a cactus (*Opuntia imbricata*). Therefore, 1500 m might represent an approximate upper ecological limit for *A. tesselata* in Colorado. In contrast, the new elevation record of 2138 m for *A. neotesselata* in Teller County is similar to the maximum elevation (2103 m) reported for *A. neotesselata* in Fremont County (using the name *Cnemidophorus tessellatus*) by Banta and Kimmel (1965). This is slightly lower than the upper elevation of 2286 m reported for *A. sexlineata* in Colorado by Banta (1968b). Therefore, based on these data, the upper elevation boundary for *A. neotesselata* is approximately 600 m higher than that of *A. tesselata*. In addition, the northern distribution record of *A. neotesselata* from FCNC, El Paso County,

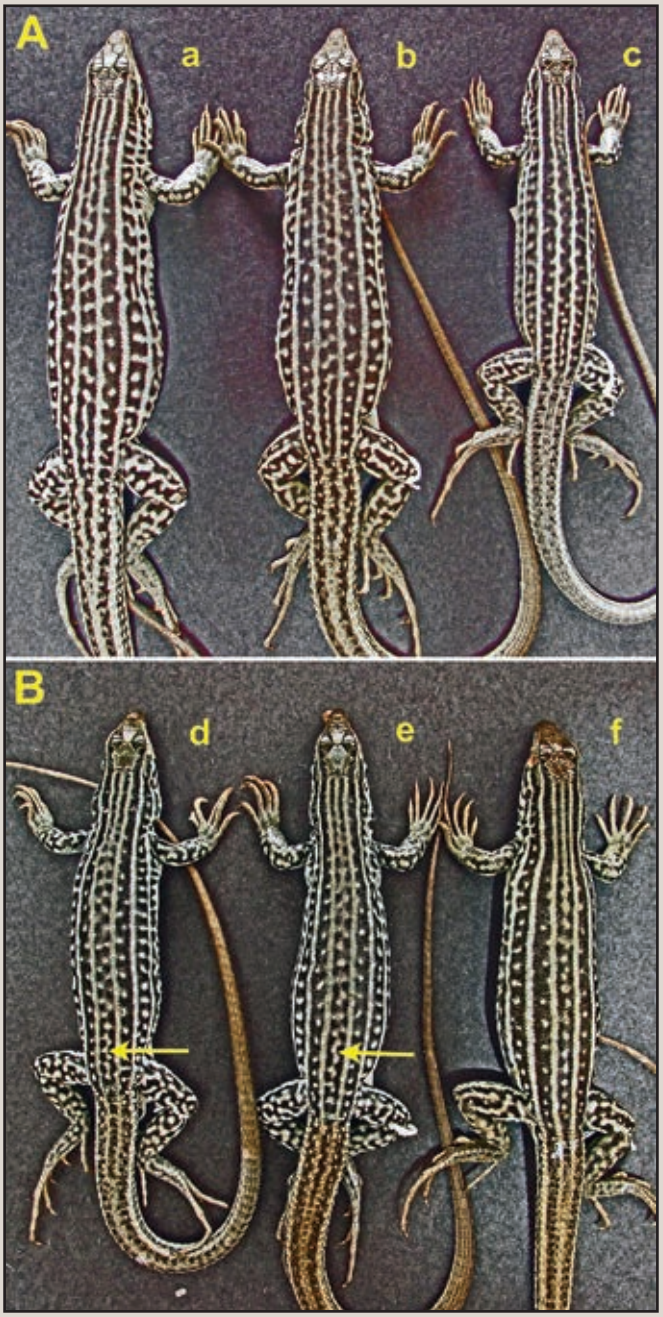

FIG. 4. Voucher specimens of *Aspidoscelis neotesselata* of pattern class A (a–e), and pattern class D (f). A. Shelf Road, Teller County, Colorado: a. HLT 399: 101 mm SVL; b. HLT 400: 96 mm SVL; c. HLT 401: 78 mm SVL (all collected 21 August 2014). B. Fountain Creek Nature Center, El Paso County, Colorado; d. HLT 396: 83 mm SVL (collected 18 July 2014); e. HLT 397: 88 mm SVL; f. HLT 398: 88 mm SVL (both collected on 15 August 2014). See Appendix 3 for details. Photographs are not at same scale. We identified specimen f (HLT 398) as pattern class D based on relatively uncluttered dark fields and a linear series of spots, rather than a short irregular-line (arrows), as found posteriorly in the vertebral field of pattern class A (also seen in specimens a–c). HLT 398 also had pale-tan spots and stripes, rather than gray (as shown for specimens a–e). Multivariate analysis of meristic characters confirmed this visual identification of specimen f as pattern class D.

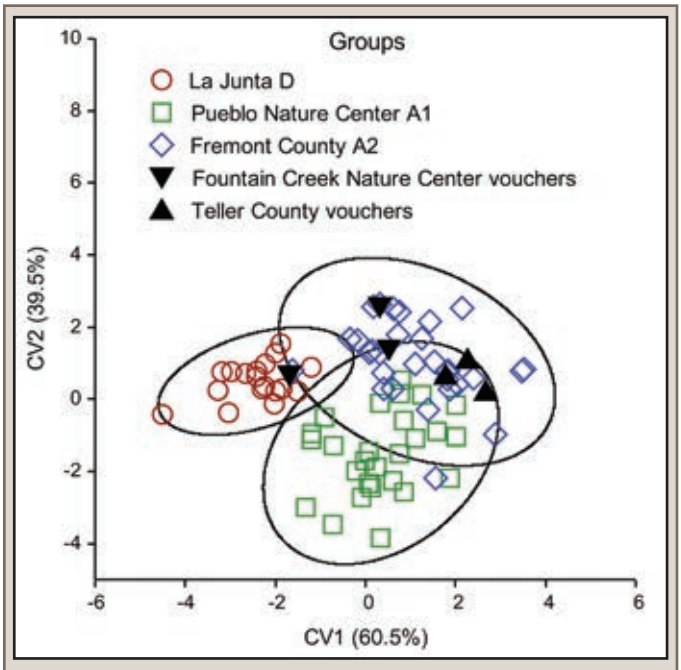

FIG. 5. Scatterplot of canonical variate scores CV1 and CV2 based on functions derived from CVA of three reference samples (a priori groups) of *Aspidoscelis neotesselata* from southeastern Colorado: group A1: 27 specimens from Pueblo Nature Center, Pueblo County; group A2: 30 specimens from north of Florence, Fremont County; group D: 18 specimens from La Junta, Otero County. Scores for six voucher specimens from Fountain Creek Nature Center, El Paso County, and Shelf Road, Teller County, were from classifications of vouchers, treated as "unknowns," by the CVA. Axis percentages are proportions of variation accounted for by canonical variates CV1 and CV2, and ellipses enclose the 95% confidence limits of the score distributions.

is only ca. 6 km farther north than the northern record from Teller County, suggesting that a northern latitudinal limit may have been identified for *A. neotesselata* in its natural range.

A number of alternative scenarios could account for the presence of pattern class A at FCNC. First, habitats associated with Fountain Creek might have served as a dispersal corridor from Pueblo to FCNC, a distance of approximately 51 straight-line km (Fig. 1). Pattern class A occurred along Fountain Creek within the city limits of Pueblo in the 1960s (Walker et al. 1996), and also north of Pueblo (Fig. 1) as documented by a specimen collected in 1965 near Fountain Creek, via Overton Road, 12.4 km N of Hwy U.S. 50 (G. Hammerson, pers. comm.). There is a distributional gap between this record and FCNC. On 9 August 1994, Hobart Smith, David Chiszar, and Lauren Livo searched the vicinity of Fountain Creek in El Paso County, approximately 15 km N of the Hammerson record. Representatives of *A. sexlineata*, but not *A. neotesselata*, were encountered. However, our multivariate evidence identified the two voucher specimens of pattern class A from FCNC as representatives of group A2 from Fremont County, not A1 from Pueblo County, thereby contributing no support for arrival by northward dispersal along Fountain Creek. It is unlikely that pattern class A arrived at FCNC by dispersal from the east. Banta (1968a) used a pitfall trapline (July through October, 1963) to assess the herpetological community 22.5 km E of FCNC. Fifty-seven individuals of *A. sexlineata* were among the 586 reptiles and amphibians captured, but *A. neotesselata* was not represented.

Although human introduction of pattern class A into FCNC cannot be excluded, there are potential source arrays of pattern class A located on the U.S. Army Fort Carson Installation southwest of FCNC (Fig. 1; Appendix 3). Fort Carson arrays have

not been sampled and statistically confirmed as representing group A2, but they are geographically proximate to the A2 reference sample from Fremont County (Fig. 1; Appendix 3). The Teller County array of pattern class A is also linked to the A2 reference by the strong, multivariate classification of voucher specimens to that group and by a chain of observations north of Cañon City (Fig. 1, Appendix 3).

Similarly, the new northern record for pattern class B in Pueblo County is connected to the source array of group B2 at PCD by a well-defined path of observations along Chico Creek, (Fig. 1).

The discovery of a new pattern class of *A. neotesselata* (pattern class D) was an accidental surprise based on the capture, by nine-year old Michelle Keefer, of an individual of pattern class D that had wandered a short distance from its highly localized range within the city limits of La Junta (Walker et al. 2012). Therefore, the discovery of an individual of pattern class D at FCNC was unexpected. Although dispersal from the small local array of pattern class D at La Junta across 128 km of questionable habitats seems unlikely, there are other possible explanations for its presence at FCNC.

First, pattern class D might have been introduced into the FCNC area. The inherent capacity of *A. neotesselata* to establish an array following introduction is illustrated by a self-sustaining array of *A. neotesselata* in Grant County, Washington, approximately 1600 km NW of its natural range in Colorado (Weaver et al. 2011). That human introduction might have been involved in the geographic distribution of some of the arrays of *A. neotesselata* in Colorado is illustrated by the following example. On 29 May 2004, Joey Kellner, Paul Differding, and Melissa Van Dreese photographed an adult *A. neotesselata* (pattern class A) located approximately 1.61 km from the nearest road in Chatfield State Park, Douglas County, Colorado. It is unknown whether this individual represented an intended release or inadvertent transport to the area. Although J. Kellner checked the observation area several times in subsequent years, *A. neotesselata* was not reencountered. The Chatfield State Park locality is approximately 94 straight-line km N of FCNC and has an elevation of approximately 1724 m. According to our evidence, the latitude of Chatfield State Park exceeds the tolerance boundary for the perpetuation of arrays of *A. neotesselata* in Colorado.

A second possibility is that pattern class D appeared at FCNC by expression of an alternative developmental pathway in one or more eggs of an individual of pattern class A at that locality. Pattern classes A and D are members of the same basic morphological subgroup (subgroup A: groups A1, A2, and D versus subgroup B: groups B1, B2, and C: Taylor et al. 2015). They have similar color pattern features (Fig. 4), but statistical differences can be revealed by quantification of color pattern characters (Walker et al. 2012). Similarities between pattern classes A and D extend to ranges of variation for the univariate meristic characters used in the present study. Of the seven characters analyzed, GAB was the only character in HLT 398 (FCNC D) with a value (72) outside the range limits (74–90) of reference samples A1 and A2 (Table 1). However, if pattern class D originated at FCNC from an individual of pattern class A, the morphological link to that event is tenuous. Our CVA provided a probability of only 2% that HLT 398 represented group A2 rather than pattern class D. Specimen HLT 398 was 88 mm in SVL when collected, which exceeds the average size of 102 gravid females of *A. neotesselata*: SVL = 84.8 ± 0.72 SE, 68–101 (Taylor et al. 2006b). If HLT 398 had originated at FCNC, it would have been a potential contributor to several reproductive seasons of recruitment. If pattern class D is established and sympatric with pattern class A at FCNC, this can be ascertained by photographic evidence, and this investigation will begin in 2015.

Aspidoscelis neotesselata is endemic to southeastern Colorado (Walker et al. 1997). It is regarded as a species of special concern by Colorado Parks and Wildlife, is ranked as Near Threatened in the 2014 IUCN (International Union for the Conservation of Nature) Red List, and is currently under consideration for listing under the Endangered Species Act (http://www.fws.gov/southeast/candidateconservation/pdf/Petition_53AmphibiansReptiles.pdf, submitted 11 July 2012). Contemporary distribution information on *A. neotesselata*, such as presented herein, and continuing efforts to develop standardized monitoring protocols; e.g., Great Plains Reptile Monitoring Project (www.reptilemonitor.org), should contribute to understanding its status in nature and facilitating decisions on appropriate management protocols.

Acknowledgments.—Don Erickson discovered *A. neotesselata* at Fountain Creek Nature Center, and we extend our thanks for permission to use his photographic documentation. Thanks to Nancy Stone Bernard, Supervisor of FCNC and Tim Wolken, Community Services Director, for information on sighting locations and permission to collect voucher specimens. Voucher specimens and reference samples were collected under the provisions of Scientific Collecting License HP772 issued to HLT by Colorado Parks and Wildlife, Department of Natural Resources. We thank Libby Henits, Special Licensing Coordinator, CPW, for facilitating license addenda as arrays of *A. neotesselata* in El Paso and Teller counties were brought to our attention. We thank U.S. Army, Pueblo Chemical Depot (access coordinated by K. M. Canestorp, U.S. Fish and Wildlife Service and operations security approval facilitated by Clark Jones, U.S. Fish and Wildlife Service) for permission to collect a sample of *A. neotesselata* at PCD. We thank Roger Peyton, Forestry and Natural Resources Section, Directorate of Public Works, Environmental Division, Fort Carson, for facilitating operations security approval for records of *A. neotesselata* on Fort Carson Military Installation. Collection of samples on the Pinyon Canyon Maneuver Site was approved by U.S. Army (access coordinated by R. Bunn, DECAM, Ft. Carson Army Installation); on-site assistance was provided by M. Klavetter and D. Sharps. We thank Tim Warfel for alerting us to photographic documentation of *A. neotesselata* at Chico Basin Ranch, and Duke Phillips and Michael Moon for permission to conduct research on that property. The Colorado State University survey efforts conducted by Celina Bycenski, Devin Jacobs, Jake Milford, Molly Parren, Ed Schmal, Melissa Thompson, and Beth Wittmann were enhanced by valuable advice provided by Cameron Aldridge and Larissa Bailey. Funding for that effort was provided under a competitive State Wildlife Grant in cooperation with the U.S. Fish and Wildlife Service's Wildlife and Sport Fish Restoration Program, Colorado Parks and Wildlife, Texas Parks and Wildlife, Colorado State University, Colorado State Land Board, and the U.S. Geological Survey. We thank Robert Day for facilitating access to Fort Carson for the Colorado State University survey crews. We are grateful to Steve Wilcox for assistance in the field and technical assistance in preparing Fig. 3. We appreciate the careful reviews of the manuscript provided by William B. Neaves, Charles J. Cole, and K. M. Canestorp.

APPENDIX 1

Morphological meristic characters: **L-breaks**: bilateral count of number of dark disruptions (breaks) in the pale lateral stripe. Pale scales in the stripe may accumulate melanin during ontogeny to form localized transverse bridges between dark fields (Taylor et al. 2003). **COS**: bilateral total of circumorbital scales. **FP**: sum of femoral pores on both thighs. **GAB**: number of granular dorsal scales in a single row around midbody. The third ventral row of enlarged ventral scales, lateral to the mid-sagittal line, terminates anteriorly in the axillary region. The 15th ventral scale posterior to this terminus established the point for beginning the GAB count. **SPV**: number of scales separating clear medial margins of paravertebral stripes as close as possible to the counting position for GAB. **LSG**: bilateral total of number of lateral supraocular granules. These granular scales are located between the supraoculars and superciliary scales, and the count includes all scales anterior to a line extended from the suture line between the third and fourth supraoculars. **SDL**: number of subdigital lamellae on the fourth toe of one foot (right was chosen unless damaged).

APPENDIX 2

Reference samples of *Aspidoscelis neotesselata* assembled in 1998, and 2002–2006. HLT numbers = Regis University numbers. UTM coordinates are based on GPS datum WGS84. (1) *A. neotesselata* A1: Colorado, Pueblo County, Pueblo Nature Center (UTM 13S 528035E, 4235693N): HLT 53–74, 102, 104, 180–184; N = 29. (2) *A. neotesselata* A2: Colorado, Fremont County, several sites north of Florence including (13 S 490238E, 4250759N: southernmost site) and (13 S 490785E, 4251693N: northernmost site): HLT 85–93, 96, 98–101, 105, 106, 108–115, 190–192; Sixmile Park, Indian Springs Ranch (UTM 13S 488250E, 4261108N) : HLT 94, 95, 193–197; N = 34 (pooled). (3) *A. neotesselata* D: Colorado, Otero County: La Junta (UTM 13S 628661E, 4206010N): RU 02090, 98083, 98084, HLT 333, 335–348; N = 18. (4) *A. neotesselata* pattern class B2: Colorado, Pueblo County: U.S. Army Pueblo Chemical Depot. Found at several localities adjacent to Chico Creek, including: (13S 554931E, 4235951N: southernmost site) and (13S 554644E, 4238113N: northernmost site): HLT 1–6, 11–14, 18–22, 33–38, 107, 133–136, 178, 179; N = 28.

APPENDIX 3

New distribution records of *Aspidoscelis neotesselata*. HLT numbers = Regis University numbers. UTM coordinates are based on GPS datum WGS84.

Locations documented by voucher specimens: **Teller County:** Shelf Road north of Cañon City: HLT 399 (UTM 13S 480638E, 4279276N); HLT 400 (480320E, 4279645N); HLT 401 (480483E, 4279391N), Pattern class A, collected by Lauren Livo, Steve Wilcox, and Harry Taylor on 21 August 2014. **El Paso County**: Fountain Creek Nature Center (13S 524574E, 4284921N): HLT 396, Pattern class A, collected by HLT on 18 July 2014; HLT 397, Pattern class A and HLT 398, Pattern class D, collected by Lauren Livo, Steve Wilcox, and Harry Taylor on 15 August 2014.

Other locations (order of information for each set of coordinates: UTM Zone, Easting, Northing, Elevation, Evidence, Observer): **El Paso County:** Pattern class A: Fountain Creek Nature Center (13S 524584E, 4284914N, 1708m, Photo, D.E.); Fountain Creek Regional Park (13S 523913E, 4285600N, 1711m, Photo, W.R.M.; 13S 524649E, 4284668N, 1706m, Photo, W.R.M.); Ft. National parks, wildlife sanctuaries, and other protected areas often figure prominently in successful species conservation strategies (Stohlgren et al. 1994; Bruner et al. 2001). Protected areas can safeguard habitats for the long-term maintenance of biodiversity while at the same time serving as baselines against which biological and ecosystem change can be measured (Stohlgren et al. 1994). To realize these objectives, protected area managers require species inventories, accurate assessments of conservation status, and an understanding of existing and potential anthropogenic threats (Stohlgren et al. 1994; Castellano et al. 2003; Tuberville et al. 2005). Such information is essential for effectively targeting conservation efforts, formulating management policies, prioritizing research, and designing appropriate monitoring protocols, especially where cryptic, rare, and threatened species are concerned (Oliver and Beattie 1993; Stohlgren et al. 1994; Castellano et al. 2003; Tuberville et al. 2005).

The protected area system in Myanmar plays a pivotal role in the national and regional conservation of marine turtles (Olive Ridley [*Lepidochelys olivacea*], Loggerhead [*Caretta caretta*], Green Turtle [*Chelonia mydas*], Hawksbill [*Eretmochelys imbricata*]), and Estuarine Crocodiles (*Crocodylus porosus*). For example, Thamihla (also spelled "Thameehla") Kyun Wildlife Sanctuary hosts nesting populations of *C. mydas*, *L. olivacea*, *C. caretta*, and *E. imbricata*, Moscos Island Wildlife Sanctuary is an important nesting area for *E. imbricata* and Meinmahla Kyun Wildlife Sanctuary harbors the only viable population of *C. porosus* remaining in Myanmar and one of the few known in the region (Thorbjarnarson et al. 2000a, 2000b; Rao et al. 2002; Thorbjarnarson et al. 2006; Onishi 2009; Beffasti and Galanti 2011; Holmes et al. 2014).

Lampi Marine National Park (LMNP; 10°50'N; 98°12'E) encompasses parts of the Myeik (formerly "Mergui") Archipelago in Tanintharyi Region (formerly "Division") of southernmost Myanmar (Beffasti and Galanti 2011). Reconnaissance surveys conducted in the 1980s (Blower 1983) and 1990s (Rabinowitz 1995) documented the occurrence of marine turtles and estuarine crocodiles within the park and concluded these reptiles

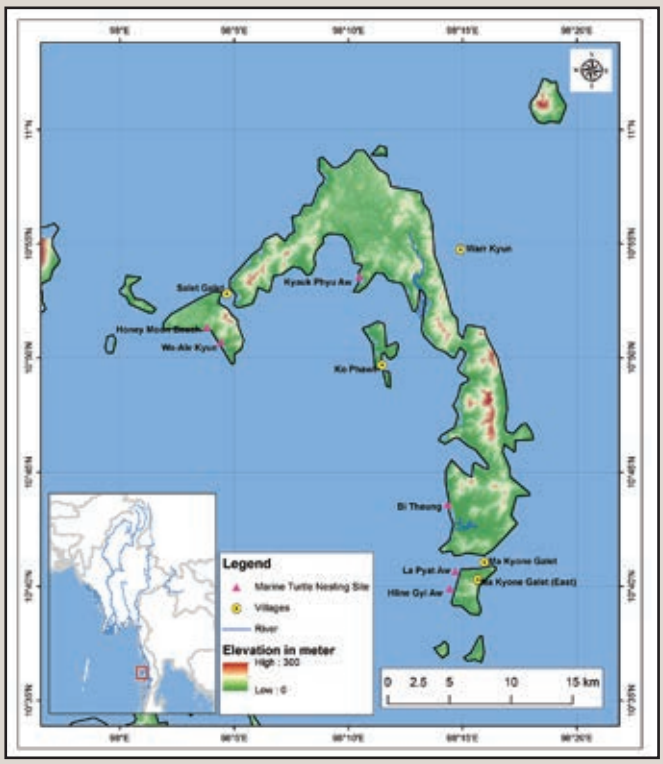

FIG. 1. Map of Lampi Marine National Park showing location of villages and marine turtle nesting sites. Inset shows location of the Park within Myanmar.

were imperiled by various anthropogenic threats. More recently, Beffasti and Galanti (2011) included three species of marine turtles on a faunal checklist of LMNP, but noted few data were available to assess their conservation status. Recent information regarding *C. porosus* in LMNP is likewise scant, although attacks on humans elsewhere in the Myeik Archipelago (Platt et al. 2012a, 2014a; www.crocodile-attack.info) suggest crocodiles could be present in the park.

This situation is not unique to LMNP as most protected areas in Myanmar lack data on the occurrence and conservation status of even common species, in large part due to the paucity of financial and technical resources available to park managers (Rao et al. 2002). More generally, there is an overall paucity of information on Myanmar's herpetofauna (Leviton et al. 2008), and in particular, few studies of marine turtles and crocodiles are yet available in the peer-reviewed scientific literature (but see Thorbjarnarson et al. 2000a, 2000b, 2006). As a first step towards addressing this need, we conducted a conservation assessment of marine turtles and estuarine crocodiles in LMNP with the objectives of 1) determining if populations of marine turtles and estuarine crocodiles occur within the park, 2) locating critical nesting habitat for marine turtles and estuarine crocodiles, 3) identifying and evaluating potential anthropogenic threats to these populations, and 4) developing a set of conservation recommendations based on our findings.

LAMPI MARINE NATIONAL PARK

Lampi Marine National Park (205 km^2; Fig. 1) was established in 1996 to protect coastal fauna and flora, particularly coral reefs (Beffasti and Galanti 2011). The park consists of Lampi Island and adjacent satellite islands, surrounded by a no-fishing exclusion zone extending offshore approximately 3.2 km from the high tide mark. The park is located approximately 25 km from mainland Tanintharyi and the intervening sea is shallow (mean depth = 12 m) with a maximum depth of 24 m. The islands within the park are characterized by steep terrain (to 455 m) supporting relatively undisturbed tropical evergreen forest (Beffasti and Galanti 2011; Blower 1983; Rabinowitz 1995). The park is well-watered with two spring-fed perennial rivers (Me Gyaung Chaung and Labi Chaung) and numerous smaller streams flowing from the uplands into the Andaman Sea. Extensive seagrass beds occur in shallow offshore waters, and mangrove forests are present along the two perennial rivers. Most of the coastline is rocky, although limited areas of sand beach are scattered around the island (Beffasti and Galanti 2011).

Although permanent settlements are prohibited on Lampi Island, four large villages (Ma Kyone Galet, Warr Kyun, Ko Phawt, and Salet Galet) containing a total of 3,000 residents are located on satellite islands encompassed by the boundaries of LMNP (Beffasti and Galanti 2011). These communities consist of ethnic Burmese, Karen, and Moken (also known as "Salone" within Myanmar). The latter are one of several semi-nomadic peoples, collectively known as "Sea Gypsies," who inhabit coastlines and islands of the Andaman Sea (Andrews 1962; Diran 2001). Harvesting marine resources (primarily fish, squid, and sea cucumbers) provides the principal source of income for island communities (Beffasti and Galanti 2011; Platt et al. 2014b). Wildlife and forest resources within LMNP are completely protected under Myanmar law; however, commercial poaching of wildlife, often by organized gangs from mainland urban centers, has been reported, and illegal timber-felling is widespread, but largely confined to the vicinity of permanent settlements (Rabinowitz 1995; Beffasti and Galanti 2011; Platt et al. 2014b). In addition to national protected area status, LMNP is recognized as an ASEAN Heritage Site and an Important Bird Conservation Area (Beffasti and Galanti 2011). The natural and cultural resources of LMNP are described in greater detail by Beffasti and Galanti (2011) and Platt et al. (2014b).

METHODS

We conducted fieldwork in LMNP from 10–21 December 2013. During this period we traveled throughout the park, stopping at villages and fishing encampments where we conducted semi-directed, opened-ended interviews (Martin 1995; Gilchrist et al. 2005) of fishermen and other knowledgeable individuals regarding the past and present occurrence of marine turtles and crocodiles, local ecological knowledge (*sensu* Anadón et al. 2009) about these species, folk taxonomy (*sensu* Berlin et al. 1966), the whereabouts of marine turtle and crocodile nesting sites, exploitation of turtles and crocodiles, fishing practices, and potential threats to turtles and crocodiles. While recognizing the limits of local ecological knowledge (Huntington 2000), our experience (Platt et al. 2004, 2005; Thorbjarnarson et al. 2006) and that of others (Thirakhupt and van Dijk 1995; Zhou et al. 2008; Anadón et al. 2009; Kanagavel and Raghavan 2012) indicates such individuals can be reliable sources of information concerning the occurrence, abundance, natural history, and local exploitation of turtles and crocodilians.

In accordance with the format of a semi-directed interview, we asked informants a series of questions that included standard questions prepared in advance and others that arose during the course of conversation. We guided the discussion, but the direction and scope of each interview was allowed to follow the

TABLE 1. Vernacular names of marine turtles found in Myanmar.

Species	Vernacular name and comments
Marine turtles (generic name)	*Pinle Leik* = Sea Turtle
Dermochelys coriacea	*Leik Zaung Lyar* = Star Fruit Turtle; name based on resemblance of carapacial ridges to longitudinal ridges on fruit of *Averrhoa carambola*.
Caretta caretta	*Leik Khway* = Dog Turtle; facial appearance, particularly prominent eyes, is said to be suggestive of a domestic dog.
Chelonia mydas	*Pyin Thar Leik* = non-descriptive name of uncertain meaning.
Eretmochelys imbricata	*Leik Kyat Tu Yway* = Parrot Turtle; name derived from the distinctive beak which resembles that of a parrot.
Lepidochelys olivacea	*Leik Laung* = Immature Turtle; so named because adults of this species are smaller than other marine turtles.

TABLE 2. Marine turtles found during a survey of Lampi Island Marine National Park, Myanmar in December 2013.

Species	Comments
Dermochelys coriacea	Fisherman stated that a small turtle (CL ca. 40 cm) fitting the description of a leatherback was found dead on a baited hook set in offshore waters in 2012.
Chelonia mydas	Carapace (CL = 415 mm) in possession of a fisherman in Ma Kyone Galet; reportedly removed from a turtle found dead on a nearby beach.
Eretmochelys imbricata	A disintegrating carapace (CL = 273 mm) obtained from a villager in Ma Kyone Galet who recovered it from a nearby beach; carapacial and plastral scutes along with bony elements found during a search of Honey Moon Beach.

participants' train of thought (Huntington 1998). Semi-directed interviews are more of a conversation than a typical question and answer session, and rather than rigidly adhering to a set of prepared questions, the interview provides an opportunity for collecting and discussing unanticipated information (Huntington 2000; Gilchrist et al. 2005). We conducted interviews of individuals as well as groups ranging in size from 3 to 36 people. Interviews were conducted by native Burmese speakers and later translated into English and transcribed. During interviews we also asked to examine any turtle shells that might be available in villages. We then measured straight-line carapace length (CL) with tree calipers (± 1 mm) and photographed each specimen. We later visited beaches where marine turtles were reported to nest as well as other sites that appeared likely nesting habitat. At each site, we searched for crawls (trackways made by nesting female turtles), nests, and other signs of activity. Crawls were identified on the basis of characteristics outlined in Pritchard and Mortimer (1999). Interview transcripts, voucher photographs of specimens, and field notes are archived in the Campbell Museum, Clemson University, Clemson, South Carolina, USA. Place names are in accordance with a national gazetteer currently being compiled by the Myanmar government. We determined geographic coordinates (India-Bangladesh Datum) with a Garmin® GPSmap76.

RESULTS

Marine turtles.—We interviewed about 110 villagers (ca. 83 men and 27 women) at various locations in LMNP during this survey. Obtaining a precise count proved difficult because interviews were often conducted in a group setting and individuals tended to wander in and out of the meeting venue. The information on marine turtles that we obtained often proved difficult to categorize to species as most people refer to marine turtles (except *D. coriacea*) generically (*Pinle Leik*) without distinguishing among species. Although vernacular names are available for each species (Table 1), these are apparently used by only the most knowledgeable individuals. We nonetheless were able to document the occurrence of *D. coriacea*, *C. mydas*, and *E. imbricata* within LMNP. Our records of *C. mydas* and *E. imbricata* are based on physical remains obtained from villagers or found while searching beaches, whereas our inclusion of *D. coriacea* is based on information provided by two fishermen (Fig. 2; Table 2). The physical remains we examined originated from dead turtles that washed ashore. We found no evidence for the occurrence of *C. caretta* or *L. olivacea* during our survey. A group of divers (N = 8) who harvest sea cucumbers (Echinodermata: Holothuroidea) from October–April reported encountering at least one marine turtle during about 50% of their nocturnal dives.

According to our informants, *C. mydas* figures prominently in Moken *Nat* worshiping practices. In Moken culture, *Nats* are spiritual guardians of the land- and seascape that must be properly propitiated; those who fail to do so risk divine retribution in the form of misfortune, sickness, or even death (Spiro 1967). Each of the two Moken communities in LMNP annually sacrifices a single large subadult or adult *C. mydas* to sea-dwelling *Nats*. The source of the turtles used in this ceremony is unclear, but most are probably captured from waters within or adjacent to the park. Importantly, we found nothing to suggest nesting female turtles are harvested for this ceremony. As part of this *Nat* worshiping ceremony, the turtle is killed and beheaded;

FIG. 2. Carapace of Green Turtle (*Chelonia mydas*) (above) and Hawksbill (*Eretmochelys imbricata*) (below) obtained from fishermen in Ma Kyone Galet. Both turtles were found dead on beaches in Lampi Marine National Park.

TABLE 3. Geographic coordinates of beaches used by nesting marine turtles in Lampi Marine National Park, Myanmar.

Beach	Latitude (°N)	Longitude (°E)
Bi Thaung	10.7265	98.2390
Hline Gyi Aw	10.6652	98.2350
Honey Moon Beach	10.8556	98.0633
Kyauk Phyu Aw	10.8930	98.1746
La Pyat Aw	10.6778	98.2445
Wah Ale Kyun	10.8453	98.0735

the head is proffered to the *Nats*, while the meat is consumed in a raucous village feast. Consumption of turtle meat outside of this ceremony is believed offensive to the *Nats* and could invite misfortune upon the community. We found no evidence that other ethnic groups dwelling within the park consume marine turtles. However, we cannot rule out this possibility owing to the reticence of informants to discuss illegal practices.

We identified six beaches in LMNP used as nesting sites by marine turtles: Bi Thaung, Kyauk Phyu Aw, Wah Ale Kyun, Honey Moon Beach, Hline Gyi Aw, and La Pyat Aw (Table 3; Fig. 1). In general, these beaches are characterized by a wide expanse of deep sand fronted by low dunes with a deep-water approach. Evidence of recent nesting activity was noted on Wah Ale Kyun and La Pyat Aw. We found two fresh (< 48 h) crawls made by nesting females at Wah Ale Kyun on 15 December 2013; large holes excavated at the apex of each trackway and numerous human footprints indicated fishermen had harvested both clutches. Based on crawl width (>100 cm), parallel lines of symmetrical flipper marks, and straight, well-defined tail-drag marks, we attributed these crawls to nesting female *C. mydas*. We also found an indistinct crawl and large excavation on La Pyat Aw where fishermen reportedly collected a clutch of turtle eggs on 6 December 2013. No sign of recent (<1 month) nesting activity was found at the other beaches.

Based on information provided by fishermen, we estimate that about 20 clutches of marine turtle eggs are annually collected from various beaches in LMNP. We were unable to determine which species of turtles nest on these beaches because informants invariably used the generic *Pinle Leik* when describing nesting activity. Most nesting is said to occur from early November through late March. Fishermen opportunistically monitor nesting beaches during this period, follow any tracks they find, and harvest the eggs, which are sold in local markets or retained for domestic consumption. Fishermen receive 100 Myanmar Kyats per egg (about US $0.10) and a large clutch represents a significant income if sold. According to observations made by our informants, semi-feral dogs (*Canis familiaris*) and monitors (*Varanus* sp.) also excavate nests and consume turtle eggs in LMNP. Although we observed numerous macaques (*Macaca* sp.) on beaches in LMNP, these primates were surprisingly not among the nest predators described by informants.

In addition to anthropogenic nest predation, our informants identified several other potential threats to marine turtles in LMNP. Foremost among these are commercial trawlers that regularly, albeit illegally, operate within the exclusion zone surrounding LMNP. Interviewees were unanimous in their condemnation of commercial trawlers (often foreign-owned boats) which frequently damage or sweep away artisanal fishing gear. We likewise observed fishing trawls legally operating in shallow waters just beyond the exclusion zone on several occasions during our survey. Other potential threats to marine turtles identified by interviewees include long-line fisheries (lines of baited hooks, sometimes extending >1 km) and dynamite fishing. Fishermen also reported occasionally finding marine turtles entangled in discarded monofilament fishing nets; if alive, the turtle is cut free and any wounds are treated with turmeric powder, which is believed to promote healing. About 50% of our informants had found dead marine turtles or their remains on area beaches within the past five years.

In contrast to commercial fisheries, the artisanal fishers we interviewed claimed to capture few marine turtles either intentionally or as by-catch. Artisanal fishermen maintain that they respect marine turtles as long-lived organisms and believe that to kill such an animal will bring misfortune to an individual. Our examination of floating wire cage traps (N = 30), one of the most common methods used by artisanal fishers to catch fish and squid in LMNP, suggests these pose little threat to marine turtles because the diameter of the funnel-shaped opening is too small to permit entry except by the smallest of turtles.

Estuarine Crocodiles.—Our interview data suggest *C. porosus* is no longer extant within LMNP. Indeed, <25% of our informants had knowledge of crocodiles, but because one of the two pe-

rennial rivers on Lampi Island is known as Me Gyaung Chaung (= Crocodile Creek), most people assumed crocodiles once occurred locally. Several older individuals stated that in the past, crocodile eggs were harvested for domestic consumption and juveniles and adults were captured and sold to buyers in neighboring Thailand. A subadult *C. porosus* (TL ca. 150 cm) we examined at a monastery in Ma Kyone Galet was reportedly captured on the coast of Rakhine State near the Myanmar-Bangladesh frontier and transported to Lampi Island for exhibition as a curiosity. In contrast to Lampi Island, our informants stated crocodiles persist in other parts of the Myeik Archipelago. Two *C. porosus* (TL ca. 180 and 300 cm) believed responsible for a spate of attacks on humans were killed in 2013 near Mine Twin Village (Kyun Su Township, Ye Ngan Aw Group), approximately 90–120 km N-NW of LNMP.

Discussion

Marine turtles.—Our survey documented the occurrence of three species of marine turtle within LMNP, which are classified as Endangered (*C. mydas*) and Critically Endangered (*D. coriacea* and *E. imbricata*; IUCN 2014; Wallace et al. 2011). Our results complement an earlier survey that reported *C. mydas, L. olivacea*, and *C. caretta* in the park (Beffasti and Galanti 2011). In contrast to our findings, neither *E. imbricata* nor *D. coriacea* had previously been reported in LMNP (Beffasti and Galanti 2011). The occurrence of *E. imbricata* and *C. mydas* in LMNP is especially encouraging because both species are endangered and the former is approaching extinction in Myanmar (Thorbjarnarson et al. 2000b; Limpus 2012; Holmes et al. 2014). Our record of *D. coriacea* is likewise important as this species is considered the rarest marine turtle in Myanmar (Maxwell 1911; Thorbjarnarson et al. 2000b).

Based on characteristics of turtle crawls, the species known to inhabit area waters, and reports from nearby Moscos Island (Beffasti and Galanti 2011; Limpus 2012), it is probable that most clutches deposited on beaches in LMNP are those of *C. mydas* and *E. imbricata*. Nesting populations of both species in Myanmar have declined from "thousands" in the early 1900s (Maxwell 1911) to a "few tens" today (Limpus 2012; Holmes et al. 2014). Thus, even though a relatively small number of clutches are apparently deposited in LMNP, these are nonetheless extremely important from a local conservation standpoint. Protecting these nests will undoubtedly prove challenging as egg harvesting has a long history in the Mergui Archipelago (Andrews 1962) and appears to be culturally entrenched in island communities (Rabinowitz 1995). Nevertheless, nest protection should be accorded high priority by park authorities as chronic over-harvesting of eggs has been implicated in the long-term decline and near-extirpation of several species of marine turtles in Southeast Asia, most notably for *D. coriacea* in Malaysia (Chan and Liew 1996; Thorbjarnarson et al. 2000b; Chan 2006).

The construction of commercial eco-tourist resorts at two of the seven known nesting beaches in LMNP (Bi Thaung and Honey Moon Beaches) is also cause for concern. Although the presence of resorts and their security staff are likely to deter egg poachers, these establishments nonetheless pose two distinct threats to marine turtles. First, resort construction could result in the direct loss of critical nesting beach habitat. Such habitat is limited in LMNP, where most of the coastline is rocky and few suitable beaches are available for nesting turtles. Second, because neonates emerging from nests are attracted to light, any unmanaged artificial lighting generated by the resorts could disorient hatchlings, thereby increasing the time spent on beaches with the concomitant risks of predation and desiccation (Lorne and Salmon 2007).

Our study is the first to describe some of the cultural beliefs of indigenous maritime communities in southern Myanmar regarding marine turtles. The veneration of marine turtles as long-lived organisms seems to reflect a wider belief among rural Burmese that misfortune will befall anyone who intentionally harms an organism that has endured years of hardship to attain advanced age (e.g., Platt et al. 2008). Among some communities, to accidentally capture and then liberate such an animal is viewed as a means of gaining karmic merit and the release is often accompanied by an elaborate ceremony (Platt et al. 2008). The *Nat*-worshiping practices we documented among the Moken are not unusual. *Nat*-worship is widespread in Myanmar (Spiro 1967) and *Nats* are perceived as guardians of tortoises (Platt et al. 2003), some species of freshwater turtles (Platt et al. 2013a), and King Cobras (*Ophiophagus hannah*; Platt et al. 2012b). Although generally quite localized and occasionally even restricted to a single community (Platt et al. 2013a), these beliefs are nonetheless consistent with conservation objectives and can be harnessed to this end (Platt et al. 2003). For example, a conservation program for the critically endangered Burmese Star Tortoise (*Geochelone platynota*) premised on reinforcing local *Nat* worshiping practices has to date proven highly successful (Platt et al. 2014c). The cultural taboos of the Moken therefore warrant further investigation as a potential tool for marine turtle conservation in LMNP, perhaps as part of a community-based conservation initiative (see below).

The potential anthropogenic threats faced by marine turtles in LMNP are representative of those confronting marine turtles throughout the region (Chan 2006; Diamond et al. 2012; Settle 1995; TRAFFIC 2004). We consider fishing trawlers to pose the most serious potential threat to turtles in LMNP despite the existence of an exclusion zone where commercial fishing is prohibited. Although trawls deployed anywhere in the territorial waters of Myanmar are legally required to be outfitted with turtle excluder devices (TEDs), compliance is difficult to monitor and appears minimal in most areas (Aung Hlaing Win and Maung Maung Win 2012; Holmes et al. 2014). This is unfortunate because the installation of TEDs has repeatedly been demonstrated to significantly reduce drownings of marine turtles by trawls (Jenkins 2012; National Research Council 1990). When not equipped with TEDs, fishing trawls are the primary source of mortality of subadults and adults in many marine turtle populations (National Research Council 1990). Longline and dynamite fishing are also likely to pose a risk to turtles (Chan et al. 1988; Chan 2006), and although strictly prohibited by park regulations, legal enforcement to date has been weak or non-existent. However, we stress that our assessment of these threats must be considered tentative pending the completion of more detailed investigations to quantify mortality among marine turtles in LNMP.

Given the lack of historic baseline data, conclusions regarding long-term population trends of marine turtles in LMNP are at best speculative. Although encounter rates reported by fishermen suggest marine turtles are still fairly common within the protected waters of the park, illegal fishing practices appear commonplace and could be killing turtles at unsustainable levels. That said, corroborative evidence in the form of stranding and carcass surveys (Shaver and Teas 1999) is lacking and must be obtained

before this conclusion can be uncritically accepted. Moreover, the annual loss of turtle nests to predation and anthropogenic harvest must be quantified before its impact on turtle populations can be accurately assessed. What little data are available from elsewhere in Myanmar suggests a similar suite of threats has resulted in population declines among all species, including the near-extirpation of *E. imbricata* (Thorbjarnarson et al. 2000b; Limpus 2012; Holmes et al. 2014). Indeed, Limpus (2012) concluded that without dramatic improvements in the effectiveness of conservation measures, all species of marine turtles will be approaching extinction in Myanmar by 2030.

Estuarine Crocodiles.—That *C. porosus* occurred on Lampi Island within the recent past is unequivocal. Estuarine Crocodiles are known to occur elsewhere in the Mergui Archipelago (Andrews 1962), and both Blower (1983) and Rabinowitz (1995) reported fishermen collecting crocodile eggs for domestic consumption on Lampi Island. Additionally, a freshwater river (Me Gyaung Chaung) on Lampi Island is almost certainly named for the crocodiles that once inhabited it. Place names often attest to the past occurrence of fauna, flora, and habitats which are no longer extant (Platt and Brantley 1997; Sousa and García-Murillo 2001). The fact that most (but not all) informants had no knowledge of crocodiles is not unexpected given the relatively brief duration of "community memory" regarding locally extinct species (Turvey et al. 2010). Indeed, Turvey et al. (2010) demonstrated that even charismatic megafaunal species are rapidly forgotten by communities once they cease to be encountered on a regular basis.

The extirpation of *C. porosus* from LMNP probably resulted from egg collection for domestic consumption (Andrews 1962; Rabinowitz 1995) and harvesting of the demographically important adults for illegal sale to wildlife traffickers in Thailand. During the 1970s and 1980s, there was a heightened demand among Thai crocodile farmers for *C. porosus* to hybridize with the more readily obtainable Siamese Crocodiles (*Crocodylus siamensis*). Hybrid progeny are commercially desirable because they exhibit rapid growth rates, attain large body sizes, and yield high-quality skins (Suvanakorn and Youngprapakorn 1987). As far as we could determine, the last crocodiles collected from LMNP were three adults captured and sold in 1986, although eggs were still being harvested as late as the early 1990s when Rabinowitz (1995) visited the islands. Given this timeframe, *C. porosus* was probably extirpated from LMNP by 2000 or shortly thereafter.

Recommendations.—We consider the absence of effective law enforcement to be the single greatest obstacle to preserving the biological integrity of LMNP. Although existing regulations appear adequate to protect marine turtles, crocodiles, and other wildlife resources, without rigorous enforcement of these legal statutes, the continued erosion of biodiversity from the park is inevitable. This state of affairs stems not from any lack of will on the part of Myanmar conservation authorities, but is instead due to the paucity of resources available to park staff, particularly boats and communications equipment. Therefore, it is imperative that government authorities and non-governmental organizations (NGOs) tasked with managing LMNP make every effort to address this situation and adequately equip those responsible for enforcing park regulations. Without vastly improved enforcement capabilities, preventing the illegal incursions of commercial trawlers, enforcing compliance with fishing regulations, and safeguarding marine turtle nesting sites are unrealistic expectations. Eco-tourist lodges now being established within the park could play a significant part in enhancing law enforcement capacity, particularly if this role is mandated by the Myanmar government in exchange for being granted a development concession within a national park. Eco-tour operators could collaborate with Forest Department rangers and local NGOs to conduct joint patrols, report violators, provide boat transportation, and facilitate radio communication. Importantly, incentives would be aligned because eco-tour operators have a vested financial interest in maintaining and protecting the biodiversity their clients are paying to view (Zander et al. 2014).

A community-based conservation initiative (Campbell and Vainio-Mattila 2003) offers further options for strengthening the protection of marine turtles in LNMP. We recommend that such a program be developed as a partnership between park authorities, NGOs, eco-tour operators, and local communities with the goal of protecting nesting beaches, bolstering hatchling recruitment, and reducing the incidental take of larger turtles in fisheries operations. The latter is critically important, given the demographic importance of the larger size classes (Congdon et al. 1993; Heppell et al. 2003), and best addressed through a community education campaign emphasizing turtle-friendly fishing practices, proper disposal of used fishing gear (especially monofilament nets), and protection of nesting beaches. Importantly, local *Nat* worshiping beliefs consistent with conservation goals should be integrated into all levels of any community education program. Furthermore, fishing regulations mutually developed by local communities and government authorities would go far toward protecting marine turtles in the park. Such regulations are perhaps the best approach for limiting potentially harmful fishing practices and gear and designating areas closed to fishing (Johannes 2002).

As an immediate first step in implementing a community-based conservation program, we recommend that a beach-monitoring and egg collection program be initiated whereby local fishermen are recruited as "beach wardens" to monitor known nesting sites in the park. Wardens will notify Forest Department staff when a turtle has nested so the clutch can be collected and transferred to a secure incubation area for hatching. A similar program along the upper Chindwin River has been instrumental in reversing the decline of the only remaining wild population of Burmese roofed turtles (*Batagur trivittata*) in Myanmar (K. Platt et al. 2013).

Again, ecotourist resorts being constructed in LMNP could be important partners in this aspect of marine turtle conservation, especially if tasked by the Myanmar government to do so. The resorts could host and manage the hatchery and assist with transporting park staff to nesting sites, hiring beach wardens, and releasing neonates. Additionally, donations or even a small fee levied on tourists could partly offset costs incurred by the tour operators participating in the project (Meletis and Harrison 2010; Zander et al. 2014). Furthermore, the marine turtle conservation program could serve as an attraction for tourists desiring to participate in an actual conservation project. Such "experiential" tourists could be involved in monitoring beaches, collecting and transporting eggs, and releasing neonates. Similar participatory conservation programs for marine turtles have enjoyed success in the United States and elsewhere (Tisdell and Wilson 2002; Wilson and Tisdell 2003; Ballantyne et al. 2009). That said, given the brief temporal distribution of nesting activity by a what appears to be a relatively small number of females (ca. 20 nests/year), an ecotourist venture based solely on marine turtles is unlikely to prove economically viable (Troëng and Drews 2004). However, marine turtles are just one of the many natural attractions of LNMP likely to appeal to ecotourists; others include scuba diving and snorkeling, hiking, bird-watching, and viewing marine

mammals, all of which can serve as the foundation for successful ecotourism ventures.

Despite being locally extirpated, the recovery of *C. porosus* in LMNP can probably be accomplished if adequate levels of protection are afforded to crocodiles. Crocodilian populations are resilient to over-exploitation and often respond dramatically to timely and well-planned conservation measures (Bayliss 1987). For example, a 10- to 20-fold increase occurred among *C. porosus* populations in northern Australia following the enactment of legal protection (Webb et al. 2010). This dramatic response is largely due to a suite of life-history traits that crocodilians possess (e.g., high fecundity, rapid growth of offspring, high adult survival, and extended parental care of offspring) which are unique among large predators (Bayliss 1987). Given the proximity of potential source populations on other islands in the Myeik Archipelago as well as the Tanintharyi mainland (Platt et al. 2012a, 2014a) and the fact that long distance movements between widely separated island populations are commonplace among *C. porosus* (Campbell et al. 2010), natural re-colonization of Lampi Island will almost certainly occur without direct human interventions. Given the small number of likely founders, however, the time to recovery could prove lengthy.

Alternatively, translocating wild-caught individuals or reintroducing captive-bred crocodiles to LMNP could facilitate the recovery of *C. porosus* in a comparatively brief period, although we urge caution if this option is pursued by management authorities. First, capturing wild subadult or adult crocodiles from elsewhere in Myanmar (e.g., Meinmahla Wildlife Sanctuary) and releasing them on Lampi Island is unlikely to prove successful due to the tendency of translocated crocodiles to return to their original home range (Lang 1987); e.g., unidirectional movements >100 km are commonplace among translocated *C. porosus* (Read et al. 2007). Second, the demographic consequences of removing even a small number of crocodiles from Meinmahla Kyun Wildlife Sanctuary (the likely source of crocodiles for any reintroduction) are unclear and could threaten the continued viability of this small population (Thorbjarnarson et al. 2000a). That said, captive-bred *C. porosus* are available from the government-operated Thaketa Crocodile Farm near Yangon. However, the genetic integrity of this population has likely been compromised by hybridization with Siamese Crocodiles obtained from Cambodia during the 1960s (Platt et al. 2013b). Therefore, it must first be determined that any crocodiles selected for reintroduction from the farm are indeed genetically pure *C. porosus*. Moreover, because the farm has experienced repeated disease outbreaks, it is imperative that crocodiles be thoroughly screened for infectious diseases before being released into the wild (Platt et al. 2013b).

In our opinion, a more desirable option would be to obtain crocodiles for reintroduction to LNMP from a head-starting program using eggs and hatchlings collected from Meinmahla Wildlife Sanctuary. Removal of eggs and hatchlings from the wild has minimal demographic impacts on crocodilian populations and survival of head-started juveniles released into the wild is typically high (Elsey et al. 1998, 2000). Importantly, any future reintroduction of crocodiles to LMNP should be closely monitored to determine the fate of released animals (Dodd and Seigel 1991).

Acknowledgments.—We thank the Minister of the Ministry of Environmental Conservation and Forestry, Director General and Deputy Director General of the Planning and Statistics Department of the Ministry of Environmental Conservation and Forestry, Director General and Deputy Director General of the Forest Department and the Director of Nature and Wildlife Conservation Division for granting us permission to conduct this survey. Field assistance was provided by U Thein Naing Aung and Forest Department rangers from Lampi Marine National Park. Research in Myanmar was made possible by generous grants from Andy Sabin and the Sabin Family Foundation and Turtle Conservation Fund. U Than Myint, U Saw Htun, Colin Poole, and Rick Hudson were instrumental in insuring the success of our field work. We also thank Brandon Sideleau for sharing information from the Crocodile Attack Database and Ruth Elsey and Madeline Thompson for providing relevant literature. Comments by Lewis Medlock and an anonymous reviewer improved an early draft of this manuscript.

Contribution to the Reproductive Biology of *Bothrops erythromelas* (Squamata: Viperidae) in the Semiarid Region of Brazil

Although oviparity is the prevalent reproductive mode among reptiles, squamates exhibit significant reproductive plasticity, with oviparous and viviparous species in numerous clades (viperids in particular, see Fenwick et al. 2012) and with different structural adaptations in both reproductive modes. In viviparous species, embryonic development occurs entirely in the oviduct, and the embryos can be fed entirely by the vitellus (lecithotrophic viviparity) or by nutrient transfer from the mother via the placenta (placentotrophic viviparity) (Yaron 1985; Stewart and Thompson 2000).

Reproductive seasonality is a widely discussed phenomenon in squamate reptiles from temperate zones, where there are marked variations in temperature and photoperiod (Marion 1982). On the other hand, a more frequent occurrence in tropical regions is an adjustment between the reproductive period and rainfall seasonality. This tendency seems to be related to food availability, which can significantly decrease during the dry season (Janzen and Schoener 1968; Ribeiro and Freire 2011). In this sense, most data on snake reproduction refer to temperate and subtropical regions. Neotropical snakes were until recently relatively little studied with regard to reproduction (Amaral 1977; Vanzolini et al. 1980; Seigel and Ford 1987). However, this scenario has changed considerably and several studies have produced a substantial amount of information, thereby significantly increasing our knowledge about the reproduction of neotropical snakes (David and Lewis 2011; Mesquita et al. 2011; Gomes and Marques 2012; Bellini et al. 2013; Figueroa et al. 2013; Marques et al. 2013; Panzera and Maneyro 2013; Siqueira et al. 2013; Sousa et al. 2014).

The genus *Bothrops* has a biennial, seasonal reproductive cycle, exhibiting an active phase of follicular growth, mating, and gestation in one year, and a parturition phase followed by follicular quiescence in the next year (Almeida-Santos and Orsi 2002; Barros et al. 2014). The reproductive apparatus contains two ovaries and two oviducts (Gomes and Puorto 1993). Copulation occurs during the fall with a gestation between four and five months and offspring are born in the summer (Almeida-Santos and Orsi 2002). It is a widely diversified clade with origin and recent radiation in the neotropical region,

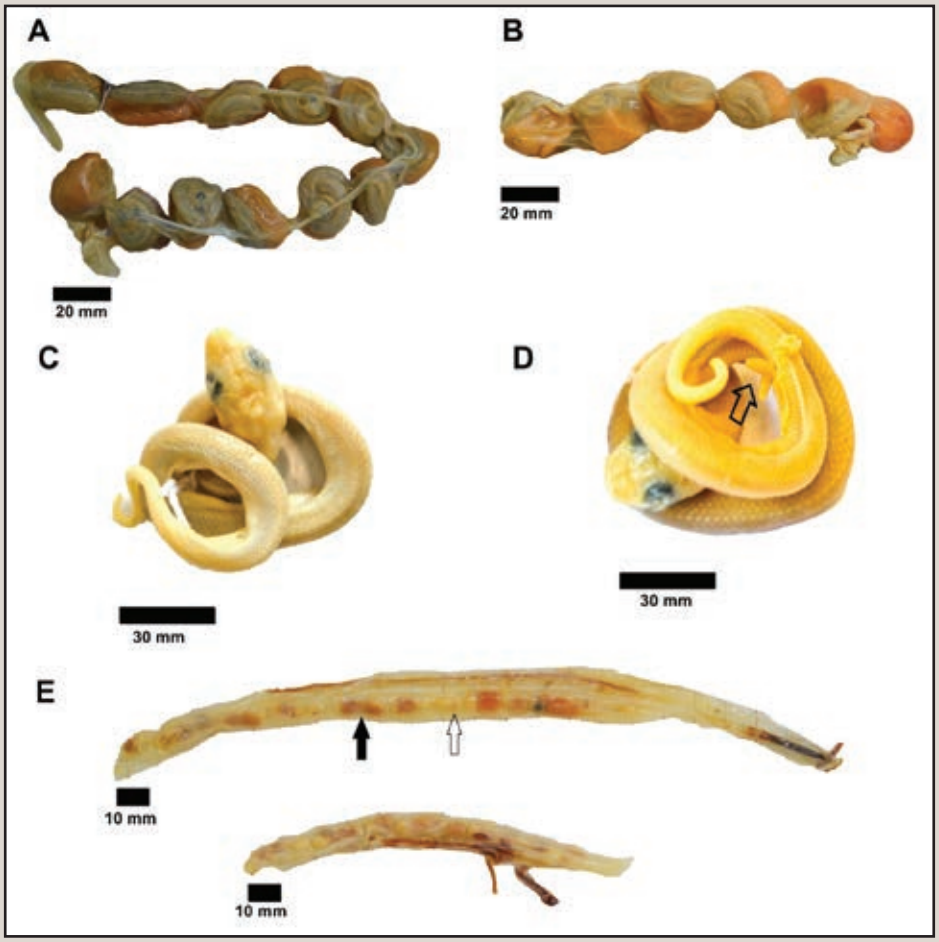

FIG. 1. Reproduction in *Bothrops erythromelas*. Right oviduct (A) with 12 embryos and left oviduct (B) with six remaining. Embryos at stage 31 of embryonic development, according to Zehr (1962): embryo with scales visible only on the body and not on the head (C), and male with hemipenes everted (arrow) visible on trunk coil (D). Right ovary (top) and left ovary (bottom) with transparent follicles without vitellus deposition (quiescent phase) (white arrow) and yellow follicles with vitellus deposition (active phase) (black arrow) (E).

and currently comprises 58 species, distributed primarily in South America (Wüster et al. 2002; Campbell and Lamar 2004; Uetz and Hošek 2014). The species *B. erythromelas*, popularly known as "jararaca-da-seca" or "jararaca-avermelhada," is widely distributed in the Caatinga (Tropical Thorny Deciduous Savanna), in addition to "Brejos de Altitude" (humid forest remnants). These forest fragments are remnants of the cycles of expansion and retraction of the humid forests that were initiated during the Pleistocene and are represented by some "islands" of humid forest that cover some isolated plateaus and mountain ranges varying from 600 to 1200 m of altitude within the Caatinga lowlands (Soares 2001). Previous studies describe the litter size (Lira-da-Silva et al. 1994), courtship and copulation behavior, and fecundity of *B. erythromelas* carried out in captivity (Silva et al. 2013). The present study aims to contribute knowledge on the reproductive aspects of *B. erythromelas* derived from nature. Here we describe the number of days in captivity until parturition, offspring morphology, and the relationship between litter size and female length.

Six *B. erythromelas* females were collected during fauna rescue efforts associated with the São Francisco River Integration Project (PISF) at different locations in the semiarid region of northeastern Brazil, two in Brejo Santo township (7.492778°S, 38,985°W), one in Jati, in Ceara state, and one each in Sertânia, Salgueiro and Petrolina (9.392778°S, 40.507778°W), in Pernambuco state.These areas are semiarid (Ab'Sáber 1974), with a short irregular rainy season concentrated in 2–3 months of each year, between January and March, and rainfall ranging between 500 and 700 mm/year. Mean annual temperatures vary from 28 to 30°C, and maximum temperatures exceed 40°C, whereas the minimum temperatures range between 17 and 20°C. Relative humidity oscillates around 30–50% in the dry season, reaching 80–90% in the rainy season (Nimer 1972).

One of the snakes collected in Brejo Santo, in December 2009, was seriously wounded and was euthanized in the field and deposited in the Herpetology Collection of the Caatinga Fauna Museum – CEMAFAUNA (voucher number MFCH 3000). The dissection was performed in December 2012 and it was found that the specimen was in the gestational phase with the presence of embryos and extra-embryonic structures. The embryonic development stage was estimated according to Zehr (1962). Biometric and body mass data were collected from these embryos. A t-test was used to determine differences in the total length of female and male embryos.

The other specimens, collected at Petrolina in August 2012, Brejo Santo in May 2013, Salgueiro in May 2013, Jati in July 2013 and Sertânia in January 2014, were held in captivity at the serpentarium of the Center for Conservation and Management of Caatinga Fauna – CEMAFAUNA, housed in 100 × 70 × 60 cm plastic boxes under a controlled temperature of 27°C until parturition. During the screening of these snakes in order to record biometric data and sex, dilation was observed in the ventral and paraventral region, suggesting pregnancy. After the offspring were born, biometric data (snout–vent length, tail length, and body mass) were measured. Spearman's correlation was used to correlate litter size with female length. Data were analyzed using SPSS version 13.0. The signicance level adopted for obtaining critical values on the tests was 0.05 (Zar 1999), and descriptive statistics are given as mean ± 1 SD.

A total of 22 offspring from five litters of *B. erythromelas* were analyzed, an average of four per litter. Offspring were born on average 157 days after the females arrived at the serpentarium, with mean length of 200.5 ± 12.61 mm (166.1–224.0 mm) and weight of 4.5 ± 1.01 g (4–6 g) (Table 1).

Twenty-one embryos were found in the dissected female, 12 in the right oviduct and nine in the left. According to Koba et al. (1970), number of eggs in the right oviduct is always greater than the left side in snakes due to its forward positioning in relation to

TABLE 1. Reproductive and morphological data of *Bothrops erythromelas* from the semiarid northeast of Brazil. Sex was determined only for those embryos from snake VI based on everted hemipenes, as described by Zehr (1962).

the left. In *B. jararaca* a larger number of eggs in the right oviduct (69.92%) was observed when compared to the left (30.08%) (Janeiro-Cinquini 2004).

All embryos were enveloped by amniotic sacs separated by tissue constriction isolating each one (Fig. 1A–B). These embryos, in an advanced stage of development, were characterized as stage 31 as described by Zehr (1962). In this phase the scales are visible only on the body and not on the head (Fig. 1C). In males, the hemipenes still everted are also visible on trunk coil (Fig. 1D). The snout–vent length of females (101.2 ± 5.5 mm, 94–110 mm, N = 12) was significantly greater than that of males (92.2 ± 5.2 mm, 87–105 mm, N = 9) (t-test = 3.831, df = 17.89, P = 0.001).

The uterine wall was distended around the embryos and below it was a thin chorioallantoic membrane. It was also observed that the ovaries were asymmetrically disposed, the right more anterior and much larger than the left. Two types of follicles were found in the ovaries: transparent or whitish, without vitellus deposition, in the quiescent phase, and yellow with vitellus deposition in the active phase (Fig. 1E).

Analysis of snout–vent length in females and litter size showed no significant correlation (r_s = –0.406, N = 6, P = 0.425), even when disregarding the female with the maximum litter size (21 embryos) (r_s = –0.616, N = 5, P = 0.269). Solórzano and Cerdas (1987, 1989), studying the reproductive biology of *Crotalus durissus durissus* and *B. asper* of Costa Rica, found a significant correlation between the total length of females and the number of neonates ($r = 0.579$, $p < 0.05$ and $r = 0.779$, $p < 0.01$, respectively). Significant correlation was also observed by Janeiro-Cinquini et al. (1990) and Janeiro-Cinquini (2004) between the length of the mother and litter size in *B. jararaca* populations.

The birth and litter records of *B. erythromelas* in December and January, notably in January (four litters), indicate that summer is the preferential reproduction period for this snake, reinforcing the observations made by Almeida-Santos and Orsi (2002) and Silva et al. (2013). The birth of newborns in the wet season is a characteristic of *B. erythromelas* shared with every species of the genus *Bothrops* studied to date (Almeida-Santos and Salomão 2002). According Barros et al. (2014) this similarity in reproductive timing in *Bothrops* species may be attributed to the influence of phylogenetic inertia in the determination of reproductive events for females. The number of days held in captivity prior to parturition for the five *B. erythromelas* at the serpentarium varied from 19 to 236 days. Although these data do not represent the total gestation period, Klauber (1972) and Aldridge and Duvall (2002) argue that variation in gestational period in pitvipers may result from sperm storage, or be influenced by temperature and/or seasonal fluctuations in food availability, making it difficult to determine the standard gestation period of the species.

There was a large difference between the number of offspring in *B. erythromelas* females who laid their litters and the dissected individual (21 offspring), even though the mothers exhibited nearly the same snout–vent length, with a mean of 573 mm. This difference in litter size may be explained by climatic fluctuations at the sites of specimen occurrence, influenced by the availability of food and the nutritional status of females (Fitch 1985; Aldridge and Duvall 2002). The number of embryos here described is much larger than that mentioned in the literature. Lira-da-Silva et al. (1994) reported 11 neonates for one *B. erythromelas* female, and Barros et al. (2014) found two to 13 embryos (average = 8) in the oviducts of five females. Lira-da-Silva et al. (1994) corroborate with the opinion of Klauber (1972) who affirm that intrinsic factors (e.g., physiological) can also interfere in the fertility rate. In this respect, marked reproductive effects that sometimes result in geographic variations can occur.

Silva-Filho (2000) followed the birth of 20 offspring of *B. erythromelas* kept in captivity, observing, based on the biometric data of newborns, that this species can be included among the smaller species of the genus *Bothrops*. However, biennial cycles are common in viperids and, considering the different factors that interfere in determining reproductive frequency in snakes and the size of their litter, it is premature to confirm, based on this sample, the proportion of the population that reproduces each year. Only a more detailed study will be able to determine the proportion of *B. erythromelas* females in the reproductive state per year and the possible fluctuations in reproductive frequency, identifying the existence of years with a larger or smaller number of reproductive females (Vitt and Seigel 1985; Ernst 1993).

Acknowledgments.—We thank the Ministério da Integração Nacional for financial support, the Center for Conservation and Management of Caatinga Fauna (CEMAFAUNA-CAATINGA) for logistics support. Dennis K. Wasko and Robert C. Jadin critically reviewed an earlier draft of this manuscript and provided many useful suggestions. Collecting permits (Permits: 042/2007, 125.r/2010 and 95/2012, Processes n° 02001.003112/2007-12 and 02001.003718/94-54) were granted by Instituto Brasileiro do Meio Ambiente e dos Recursos Naturais Renováveis (IBAMA).

Comparing Common Five-lined Skink (*Plestiodon fasciatus*) Diet Among Populations and Time

Having knowledge of an animal's diet helps to provide an understanding of its biology, ecology, natural history and can help in its conservation. Although predators are often considered dietary generalists or specialists, virtually all species show some specificity. Food items taken may also vary depending on availability in space and time. Most lizards are carnivorous and many, if not most, small to medium body-sized species are considered to be gape-limited generalized arthropod predators. Having a generalized diet or being opportunistic would allow a species greater success when food resources change through time or differ among locations.

Although the details of the Common Five-lined Skink (*Plestiodon* [formerly *Eumeces*] *fasciatus*) diet have not been thoroughly documented, the species is widely considered to be a generalized arthropod predator with a preference for arachnids, orthopterans, and blattids (Fitch 1954 and references therein). We studied diet of the Common Five-lined Skink near the northern edge of its range at Point Pelee National Park, Ontario, Canada, in 2000 (Hecnar et al. 2002), which supported this general description of the diet. In 2013 we reexamined skink diet at the same location and in the neighboring but isolated Rondeau Provincial Park, Ontario population with the goals of determining if diet changed through time or differed among

FIG. 1. The distinctive scat of a Common Five-lined Skink on the bark of a prone log. Fragments of exoskeletons from prey items give the scat a coarse texture. The scat is tipped by a cap of uric acid (white).

locations. Both locations lie within the "Carolinian Population" of the species' range in Canada where *P. fasciatus* is designated as an endangered species (COSEWIC 2015).

Methods.—We determined skink diet by examining scats following the methods we previously described (Hecnar et al. 2002). This sampling method is advantageous because it is non-invasive and non-lethal. We collected fresh scats in glass vials during population surveys in 2013 in the same area as we collected in 2000 at Point Pelee National Park, Ontario, Canada (PPNP; 41.9629°N, 82.5163°W; WGS84), and from 70 km E at Rondeau Provincial Park, Ontario, Canada (RPP; 42.2808°N, 81.8550°W). Skinks have distinctive cylindrical, straight, brown to black scats ca. 1.0–2.5 cm long (2–5 mm diam.) capped by a plug of white uric acid (Fitch 1954; Judd 1955; pers. obs.). Fragments of arthropod body parts that make up the main body of the scat give it a coarse texture and exoskeleton parts are usually obvious without magnification (Fig. 1). Compared with similar bird scats, skink scats are generally more uniform in shape, rougher and drier in texture, and the uric acid cap is less compact making them distinctive (Fitch 1954; pers. obs.). At RPP we collected some scats when individuals that we captured defecated during handling. We used these scats to determine if diet differed among sexes or age classes (male or female adult, juvenile). Sampling occurred near the peak of nesting season when size, color, and patterns allow sex and age classification. Vials were topped with 40% ethanol and transported to the lab for study. Contents of each scat were separated with probes in water and examined under a dissecting microscope to identify items to the lowest taxonomic category possible (all to Order, some to Family or species). Chitinous exoskeleton fragments were sorted to facilitate identification. Remains also tend to occur sequentially in a scat allowing counting of the number of food items (Hecnar et al. 2002).

We determined if diet changed in two different ways. First we counted the number of food items in each scat and then compared number of items between years and location using a separate variance *t*-test on square root transformed data followed by a Mann-Whitney *U* test for a non-parametric equivalent. Second, after identifying food items, we ranked items by decreasing abundance and conducted a Kendall's rank test to determine if the type of diet items changed over time or between location. This non-parametric test considers the ranked order of items by abundance between groups to determine if the groups are associated (i.e., correlated; Sokal and Rohlf 2012). If items among groups are not significantly associated, it means that diets differ. If items are significantly associated among groups (same ranked order) diets are similar among groups. Considering only abundance can inflate the perceived importance of particular dietary items (e.g., multiples of small items in individual scats) so we also conducted Kendall's rank test for the frequency of item occurrence in scats (number of scats containing each item). We used Systat 12 for all statistical analyses. Measures of central tendency are indicated with means ± 1 standard error (SE).

Results.—We collected 41 individual scats (17 PPNP, 24 RPP) containing 110 individual food items (40 PPNP, 70 RPP) among 15 arthropod groups representing eight orders (Table 1). In some cases we were able to identify items to taxa lower than order. Our most detailed identifications and incidence (% of scats) included: Family Forculidae, *Forficula auricularia*, European Earwig (49%); Family Salticidae, jumping spiders (10%); Family Rhinotermatidae, termites (7%); Family Aphidae, aphids (7%); Sub-order Zygoptera, damselflies (5%); Family Carabidae, carabid beetles (2%); and Family Ixodidae, ticks (2%). An average of 2.4 ± 0.23 items (1–5) occurred in PPNP scats and 2.9 ± 0.96 items (1–24) occurred in RPP scats. The number of items per scat did not differ between PPNP and RPP in 2013 (separate variance $t = 0.06$; 30.29 df; $P = 0.95$; $U = 229.5$; 1 df; $P = 0.12$). Similarly, number of items did not differ between PPNP in 2000 (3.2 ± 0.36 items, range 1–6, data from Hecnar et al. 2002) and 2013 (separate variance $t = 1.77$; 33.45 df; $P = 0.09$; $U = 254.5$; 1 df; $P = 0.16$). Combining data for both years at PPNP and RPP for 65 individual skinks indicates an average of 2.9 ± 0.39 SE items (1–24) occurred per scat among 15 taxonomic groups.

A high proportion of dietary items in 2013 were arachnids (Orders Arachnida, Opiliones, Acarina) at both PPNP (35%) and RPP (20%) and this was similar to PPNP in 2000 (43%). However, substantial differences in the proportion of other insect groups in lizard scats occurred at both locations in 2013 (Table 1, Figs. 2–5). Most notable was the high proportion of Dermaptera (Earwigs) at both PPNP (35%) and RPP (23%) and Isoptera (Termites) that dominated the number of diet items at RPP (41%). Kendall's rank tests indicated no association between the abundance of each type of dietary items compared between years at PPNP ($\tau = 0.07$; $N = 14$; $P > 0.1$) or between PPNP and RPP ($\tau = 0.36$; $N = 10$; $P > 0.5$)(Fig. 2). Tests using frequency of items among scats had similar results; no association between years at PPNP ($\tau = 0.01$; $N = 14$; $P > 0.1$) or between PPNP and RPP ($\tau = 0.46$; $N = 10$; $P > 0.1$) (Fig. 3).

We were able to collect 16 scats from skinks at Rondeau (4 ♀♀, 5 ♂♂, 7 juveniles) while they were being processed for another study (Table 1). Number of food items per scat did not differ among sex or age class (males 2.2 ± 1.64; females 2.5 ± 1.73; juveniles 1.7 ± 1.25; Kruskal-Wallis $H = 1.45$; 2 df; $P = 0.484$; Fig. 4). Kendall's rank test indicated no association between the abundance of each type of food items consumed among males, females, and juveniles (Taus ranged $\tau = 0.27$–0.58; $N = 6$–8; and $P > 0.05$ for all comparisons). Tests using frequency of items among scats had similar results; no association among males, females, and juveniles (Taus ranged $\tau = 0.14$–0.59; $N = 6$–8; $P > 0.1$ for all comparisons; Fig. 5).

Discussion.—In general our recent sampling confirms findings of earlier studies that Five-lined Skinks largely consume ground-active rather than flying forms of arthropods (Fitch 1954 and references within; Hecnar et al. 2002). Our results also add

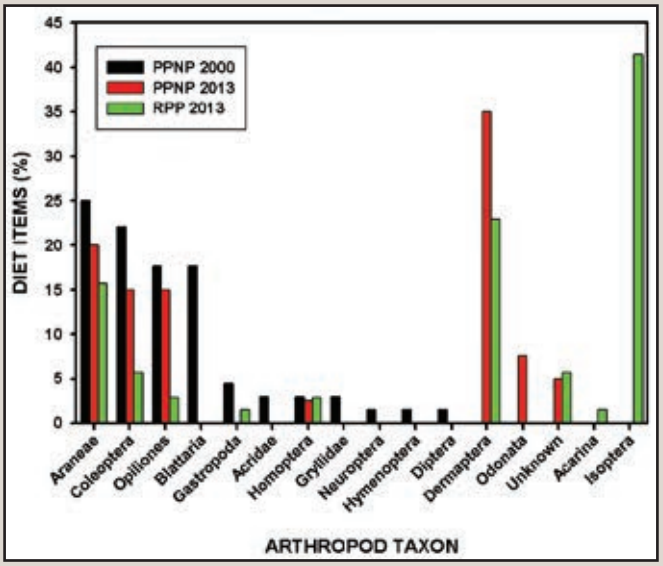

FIG. 2. Abundance of diet items by arthropod taxon found in skink scats at Point Pelee National Park, and Rondeau Provincial Park, Ontario, Canada. Data for PPNP in 2000 from Hecnar et al. 2002.

evidence of dietary differences between locations or changes over time potentially or presumably reflecting prey availability and opportunistic feeding.

Exoskeletons of individual items were sometimes missing pieces, but in most cases a sufficient number allowed some level of identification. Although considered a gape-limited predator, Fitch (1954) suggested that missing parts of exoskeletons in scats indicated that Five-lined Skinks battered larger prey items prior to swallowing. On several occasions, we observed skinks capturing and battering larger grasshoppers and harvestmen to subdue them and accommodate swallowing. Judd (1955) noted that sometimes two skinks would grasp a single food item and tear it apart.

Numbers of items per scat did not change significantly over time at PPNP or between PPNP and RPP, suggesting that skinks had the same abundance of food. Interestingly, the average number of items in scats from our samples in both years (2.9–3.2 items/scat) was nearly double the number reported from Kansas (1.67 items/scat; Fitch 1954). Skinks took a wide variety of food items at both PPNP and RPP in 2013, as they did at PPNP in 2000, with arachnids (spiders and harvestmen) forming a sizeable portion of the diet. This adds additional evidence that skinks might exhibit some preference for arachnids. We cannot demonstrate selectivity as we did not measure the array of available foods. However, the proportion of arachnids in scats appears much greater than their availability. Similarly, coleopterans (beetles) were well represented in diets. We found the remains of a carabid beetle (genus *Agonum*) in one 2013 PPNP scat, and beetles, most of which were carabids, were the second most common food item found in the 2000 analysis. This contrasts surprisingly with a study of the closely related Southeastern Five-lined Skink (*Plestiodon inexpectatus*), which indicated that they avoid eating and are repelled by secretions of the carabid beetle *Pasimachus*

subsulcatus (Witz and Mushinsky 1989). Fitch (1954) and earlier sources he cited also suggested a preference for orthopterans (grasshoppers) and blattids (cockroaches), with which our study at PPNP in 2000 concurred. However, neither group was represented in 2013 at either location (Table 1: Blattaria and Gryllidae). Ants (Family Formicidae) were also absent at both locations in 2013, and we found only one ant in a scat at PPNP in 2000. Considering that ants commonly co-occur with skinks at both sites but are essentially absent in scats suggests that they are avoided as food items as Taylor (1935) noted for the *Eumeces* group of skinks. Formic acid and other associated defensive chemicals present in ants likely deters consumption (Blum 2012).

Judd (1962) examined stomach and intestinal contents of seven male skinks captured at RPP and found remnants of 11 crickets, 2 snails, 2 spiders, 1 cockroach, 1 sow bug, and 1 caterpillar. Although his sample size was small, the nature of dietary items clearly differs from our observations at the same location 54 years later—adding further evidence to an assumption of dietary change or opportunistic feeding over time. Each of the food items found in skinks in the 1959 study (Judd 1962) also occurred in sympatric Jefferson Salamanders (*Ambystoma jeffersonianum*, [now considered Jefferson Complex at RPP] (Judd 1957). We also noted high seasonally syntopic local distribution of ambystomatid salamanders with skinks in 2013.

Despite similarities in the number of dietary items and some evidence of preferences for arachnids, other types of dietary items differed widely in both time and location. The most striking differences were the appearance of Dermaptera at both locations in 2013. Although earwigs were not recorded as dietary items at PPNP in 2000, they dominated diets in 2013. Similarly, they were the second most common diet item at RPP in 2013, following only termites. In most cases we were able to identify dermapteran fragments as belonging to *Forficula auricularia*, the European Earwig. The termite fragments were likely *Reticulitermes flavipes* (Isoptera: Rhinotermitidae), the only termite known from wild populations in the region (Raffoul et al. 2011). Two of us documented the first occurrence of a wild population *R. flavipes* for the region at Point Pelee (Raffoul et al. 2011). This species is becoming an important pest in southern Ontario cities. In recent years, the abundance and distribution of termites has expanded at PPNP and now they apparently also occur at RPP.

Our sample of food items among sex and age classes was small but indicated that number of food items per scat was not significantly different between males, females, and juveniles. Similar to our time (2000 vs. 2013) and location (PPNP vs. RPP in 2013) analyses, the types of dietary items consumed were not associated when either abundance of items or their frequency among scats were considered. This suggests sex and age classes may have dietary differences. That female and juvenile diets were not associated was somewhat surprising as they often co-occurred at nest sites when we collected our samples (Hecnar 1994). Results for sex and age class comparisons should be interpreted cautiously as sample sizes were small.

Our studies show how a simple non-invasive sampling technique can be useful for reconstructing diets of arthropod or insectivorous lizards. Scats are easily recognizable, are easy to collect, do not degrade quickly, and the identity of prey items is relatively easy to determine. Our studies now suggest that the Five-lined Skink in the Carolinian portion of its northern range is a generalist arthropod predator that appears to show some preference for arachnids, but it also demonstrates that skinks are opportunistic feeders. Dietary breadth is likely a characteristic that promotes skink survival in these highly dynamic coastal dune communities. Considering the broad overlap of geographic ranges for Five-lined Skinks with earwigs and termites, they may be important predators on these pest species. This evidence for skink predation on invasive pests and other evidence that skinks may serve as "dilution hosts" (reduce prevalence) for Lyme disease (Giery and Ostfield 2007) highlight often overlooked services reptilian species provide for humans.

Acknowledgments.—We thank Point Pelee National Park and Rondeau Provincial Park, Ontario, Canada for permission and assistance with our work, especially T. Dobbie and E. Slavik, who were our respective liaisons. Funding was provided through a Parks Canada Research contract and an OMNR SARRFO grant to SJH. Our methods were approved by Parks Canada's and Lakehead University's Animal Care Committees. All provincial and federal permits were obtained. T. Eyre and K. Myschowoda helped with fieldwork. R. Russell provided statistical advice. Helpful suggestions for revision were provided by S. Siers, R. Powell, and an anonymous reviewer.

The First Report of *Aplectana hylambatis* (Nematoda; Cosmocercidae) Associated with *Dermatonotus muelleri* (Anura; Microhylidae) from Brazil

Dermatonotus muelleri (Boettger 1885) is the only species for this genus from the family Microhylidae. This anuran is hard to find due to its fossorial habits, and it is an explosive breeder during the wet season (Nomura 2009). Concerning its helminth fauna, only specimens from Paraguay have been recorded, including the nematode *Aplectana hylambatis* (Baylis 1927) and the cestode *Ophiotaenia cohospes* Coredo, 1946 (Campião et al. 2014). In Brazil, there are records of *Aplectana* sp., a species of Cosmocercidae, and plerocercoid larvae of *Spargana* parasitizing *D. muelleri* (Bezerra et al. 2012; Campião et al. 2014). In light of this, we present the first record of *A. hylambatis* parasitizing a Brazilian anuran species, *D. muelleri*, as well as the ecological descriptors of parasitism. In addition, we also describe the morphological characterization of this nematode species.

During the rainy season in February 2013, we collected 19 specimens of *D. muelleri* from a biological reserve in the State of São Paulo (Reserva Particular do Patrimônio Natural Foz do Rio Aguapeí). The anurans were necropsied and upon discovery, nematodes were fixed with hot alcohol (70%) and then mounted on temporary slides with Lactofenol. The identification was based on Travassos (1931), Baker (1980), Vicente et al. (1991), and recent articles about the species description of *Aplectana* spp. The ecological descriptors of parasitism—prevalence (%), mean abundance (MA), and mean intensity of infection (MII)—were calculated according to Bush et al. (1997). MII and MA are presented as mean values with their standard errors.

Aplectana hylambatis was the only helminth species found in these anurans. Only 3 of 19 (15.8%) anurans examined had this parasite in the large intestine, with a total of 678 helminths detected (range: 16–553). Parasitized individuals were infected with an average of 226.0 ± 165.7 helminth individuals per host, and MA was 35.7 ± 29.3.

Family Cosmocercidae Travassos, 1925
***Aplectana hylambatis* (Baylis, 1927) Travassos, 1931**

These nematodes present marked sexual dimorphism, wherein females are slightly longer than males. Both sexes have a transversal cuticle, mouth with three lips, and a very visible excretory pore that is anterior from bulb of oesophagus (Fig. 1A). There are no plectanes at the end of males' tails, but there are some papillae distributed with number and pattern variable. The spicules are very marked and present a hook at the extremity (Fig. 1B). Females have an equatorial vulva with a salient border which is easily notable (Fig. 1C), and the majority of them present numerous thin shell eggs. Unfortunately, females of several species of Cosmocercidae have very similar morphology, thus it is necessary, often, to have the presence of males in

*In *Dermatonotus muelleri* from Paraguay, Baker and Vaucher (1986) report that descriptions of *Aplectana hylambatis* were attributed to Baker (1980), where this nematode was redescribed parasitizing *Rhinella achalensis* from Argentina.

the sample to distinguish taxa. Due to this, most descriptions address characteristics of males. The measurements of males and females are showed on the Table 1.

Aplectana hylambatis was described by Baylis (1927) in *Leptopelis aubryi* (Duméril, 1856) (Arthroleptidae) from Guinea, Africa, and it is redescribed by Baker (1980), recording this nematode in *Rhinella achalensis* (Cei, 1972) from Argentina. After this, other studies showed the morphological variation of this nematode species associated with other hosts (e.g., González and Hamann 2010; González et al. 2013). The number of caudal papillae on the posterior end of males is variable, and the two articulation parts of spicules can be seen clearly through the scanning electron microscope (González and Hamann 2010).

The papillae pattern of *A. hylambatis* can vary in some specimens associated with different species of host, but this variation is not so marked (Table 2). The spicules of specimens associated with anurans from South America (Argentine, Paraguay, and the present study in Brazil) vary from 228 µm to 350 µm in length, while the gubernaculum can measure 48–116 µm (Table 2). This cosmocercid has a wide distribution, occurring in six countries from South America (Argentina, Ecuador, Guyana, Paraguay, Peru, and Uruguay), and 22 anuran species are associated with it (Campião et al. 2014). However, in Brazilian anurans, this is the first record; *Aplectana hylambatis* has never been recorded in Brazil. This study increases the geographic distribution of this nematode.

Aplectana hylambatis, as well as other cosmocercids, is a generalist nematode parasite, but the association with *D. muelleri* from Brazil may suggest host specificity because this nematode of trophic infection has also been reported in *D. muelleri* from Paraguay (Baker and Vaucher 1986). In the present study, the exclusive parasitism by *A. hylambatis* with this population of *D. muelleri*, without cosmocercids of skin penetration, indicates that the fossorial habitat and skin secretions of this anuran may hinder infections by parasites with skin penetration (Tempone et al. 2007).

Acknowledgments.—We are grateful for financial support provided by Fundação de Amparo à Pesquisa do Estado de São Paulo (number of process: 2011/20186-6), and CAPES for financial scholarship for A. Aguiar. Specimens were collected under license number 31716-2.

Field Venom Extractions: Saving Fingers with Tubes, Forceps, and Nerf Bullets

Historically, reptile venom research has only been correlated with medical significance to humans (Weiner 1960; Shafqat et al. 1990; Earl et al. 2012; Savanur et al. 2014). Thanks to technological and analytical advancements, venomics has extended into other fields of biology such as ecology and phylogeny (Li et al. 2005; Mackessy et al. 2006; Richards et al. 2012; Heyborne and Mackessy 2013; Benard-valle et al. 2014). Proteomic techniques (e.g., electrophoretic profiling, spectrometry, transcriptomics) have been effective for exploring interspecific and intraspecific protein variability geographically and ontogenetically (Mackessy et al. 2006; Alape-Giron et al. 2008; Barlow et al. 2009; Casewall et al. 2009; Madrigal et al. 2012; Lourenco et al. 2013; He et al. 2014; Lanari et al. 2014), thus presenting new evidence for untangling the complex trajectories of venom evolution (Calvete et al. 2009; Fry et al. 2009; Casewall et al. 2009; Margres et al. 2014; Brahma et al. 2015).

In contrast to methodological advancements in venom analysis, the general procedure for extracting crude venom from live specimens remains essentially unchanged (Willemse et al. 1979; Savanur et al. 2014). The only apparent documented exceptions rely on techniques such as electrical pulsations and anesthesia (McCleary and Heard 2010; Margres et al. 2014), which present obvious limitations in the field. The traditional method for venom extraction from high-pressure delivery species (e.g., viperids and elapids) relies on manual subcranial restraint followed by venom delivery into a collection vessel, often through a membrane. Accidental envenomations during traditional extractions are accredited to human error in combination with the impressive cranial dexterity of specimens (Hayes 2008; J. Harrison, pers. comm.). Acknowledgment of this inherent danger generates logistical complications (e.g., collection permits and IACUC protocols) that might compromise or limit venom research efforts (pers. obs.).

To increase the relative safety while extracting venom, the separating tube extraction method was established and evaluated for effectiveness on terrestrial pit vipers (Crotalinae). The proposed method was designed to operate within the limitations of a field setting while minimizing stress for the specimen. It combines previously established handling techniques (Johnson 2011) with a novel concept in an attempt to eliminate direct physical contact with the snake's head.

Materials

Separating Snake Tubes.—A custom set of snake tubes were fabricated from 1-m lengths of rigid vinyl tubing (Lowes® item numbers: 652376, 652385, 652455, 432506, 432501, 443439, 443438, 35778, 35768). Finished tubes separate into two pieces when grasped at opposite ends flexed side to side. Separation points were positioned 20 cm off-center (resulting in 30 cm and 70 cm segments when separated) and the friction-dependent joints were meticulously constructed to ensure a reliable connection. Tapering directionality for the joints is depicted in Fig. 1. This layout preserves interior diameters of the shorter segments where the snake's head is exposed during extractions.

Padded Forceps for Gland Manipulation.—Curved hemostat forceps (HTS 161S3, 12") were modified to replace the extractor's hands during head positioning and venom gland manipulation (Fig. 2). The unnecessary locking mechanism was removed to prevent accidental locking. Tool-grip rubber was applied over the teeth to coat any sharp edges. Cylindrical foam was positioned over the coated teeth (13 mm diameter) to disperse pressure during gland manipulation. The foam was derived from Nerf® darts based on their availability and contrasting coloration (Nerf® product number: 62567).

Venom Collection Vessels.—Plastic beakers (50 mL) with plastic membranes were chosen for venom collection vessels. Rubber bands were utilized for securing membranes over beakers and also for fastening beakers to sturdy rocks or logs in field extraction settings. Beakers were prepped each day before entering the field to minimize set-up time. Venom was pipetted out of the membrane-covered beakers into 2-ml sample tubes and stored on ice while in the field.

Methods

The step-by-step procedure below was tested and refined via mock scenarios using various non-venomous snakes from the Herpetology Collection at the University of Massachusetts (e.g., *Pantherophis, Elaphe, Aspidites*). The technique was then tested periodically between April and July of 2014 in the field on 11 wild adult *Crotalus oreganus* (Western Rattlesnake, one extraction

FIG. 2. Modified forceps. The rubber band was used to prevent the tool from inverting accidentally during extractions when only one hand was available.

session per snake) in the Columbia River Plateau Ecoregion of Oregon and Washington, USA. These efforts were supplementary to a population genetics project. The extractor was proficient in using standard venomous snake handling equipment (regular acrylic snake tubes, tongs, hooks, and bags) and safety measures (snake proof "gators" and/or boots, multiple individuals present on site, reliable research vehicle, localities and contact information for closest antivenom-stocked medical centers). For our purposes, a venom extraction was considered successful after collecting at least 0.1 ml uncontaminated crude venom (Mackessy 2002) (Fig. 3E) while avoiding direct physical contact with snake's head. All snakes were released at respective capture locations the same day as capture. Extractions were videotaped using a Sony HD Handycam and later reviewed for potential improvements.

The following is the proposed venom extraction procedure. Extraneous details were excluded in this outline for clarity (e.g. capture and release strategies, additional specimen processing, proper use of bags and other handling equipment, preparing and sterilizing extraction equipment). It is presented as a second-person instructional narrative to concisely highlight timing details for the reader and minimize misinterpretation. I believe the best treatment for snakebite is prevention.

PROPOSED PROCEDURE

1. *Set up Extraction Station.*—Designate a sturdy surface to serve as the extraction station (e.g., tailgate, picnic table, flat boulder, log). Using one or two rubber bands, secure the prepped collection vessel to a flattened stone or similar object (approximately the size and weight of a brick). Minimal mobility of the collection beaker is preferable. Stage the padded forceps next to the collection vessel for ease of access. Assemble the separating tubes and make sure all the joints are intact and functional. Assess the surroundings for potential obstacles and confirm the location's suitability for venom extraction.

2. *Tubing the Snake.*—Select the smallest diameter tube which accommodates the snake's midsection. If uncertain, always undershoot and adjust accordingly. The goal is not to prevent the snake from "turning around" but rather to minimize body contortions for maximum control. Correct tube size is crucial for optimizing safety and yield. While holding the tube at the very end of the larger segment, guide the snake into the opposite opening using snake tongs and gently coax it inside until the head is within a couple centimeters of the joint. This may be performed in a bucket to help contain the snake. When ready, drop the tongs and with that hand quickly grasp both the snake body and tube at the opening. The grip should be relaxed yet firm. With the tubed snake in hand, slowly relocate to the extraction station. Support the snake's un-tubed posterior to avoid damaging the vertebrae.

3. *Venom Extraction.*—Position the tube on a flat surface with the snake's head facing away. Carefully feed more of the body into the tube until the head passes over the joint seam (Fig. 3A). Grab the far end of the tube and wiggle using moderate effort until the joint gradually releases. Take your time with this step. The separation of the two halves exposes the snake's head from the smaller segment (Fig. 3B). Use the padded forceps to gently restrain the snake directly behind the head. Lift the snake over to the venom collection beaker and offer it the membrane surface (Fig. 3D). If the snake is unwilling to bite, a gentle nudge against the beaker is sufficient to elicit a bite. After fang penetration, reposition the forceps over the venom glands and apply pulsating pressure. The effort is comparable to squeezing a tube of toothpaste. Cease gland manipulation after approx. 30 seconds (or when enough venom is delivered) and allow the snake to release itself. If a fang becomes stuck gently maneuver it out using the forceps. Promptly re-attach the tube segments following the extraction as a safety precaution.

RESULTS

All extractions attempted were successful with 0.10 ml or higher yields and no direct contact was made with the exposed heads. Snout vent length of the 11 snakes ranged from 62 cm to 99.8 cm, and extraction stations included the hood and trunk space of our research vehicle (Jeep Grand Cherokee), pickup truck tailgates, and boulders at capture locations.

DISCUSSION

On two occasions a fang penetrated through the rubber band securing the collection vessel and on one occasion a fang missed the vessel completely. However this had no effect on the extractor's safety and sufficient yield was still attained. If a snake was extracted at the place of capture, the elapsed time between capture and release was less than 20 min (making it our preferred method). This would not be possible if the procedure relied on anesthetics

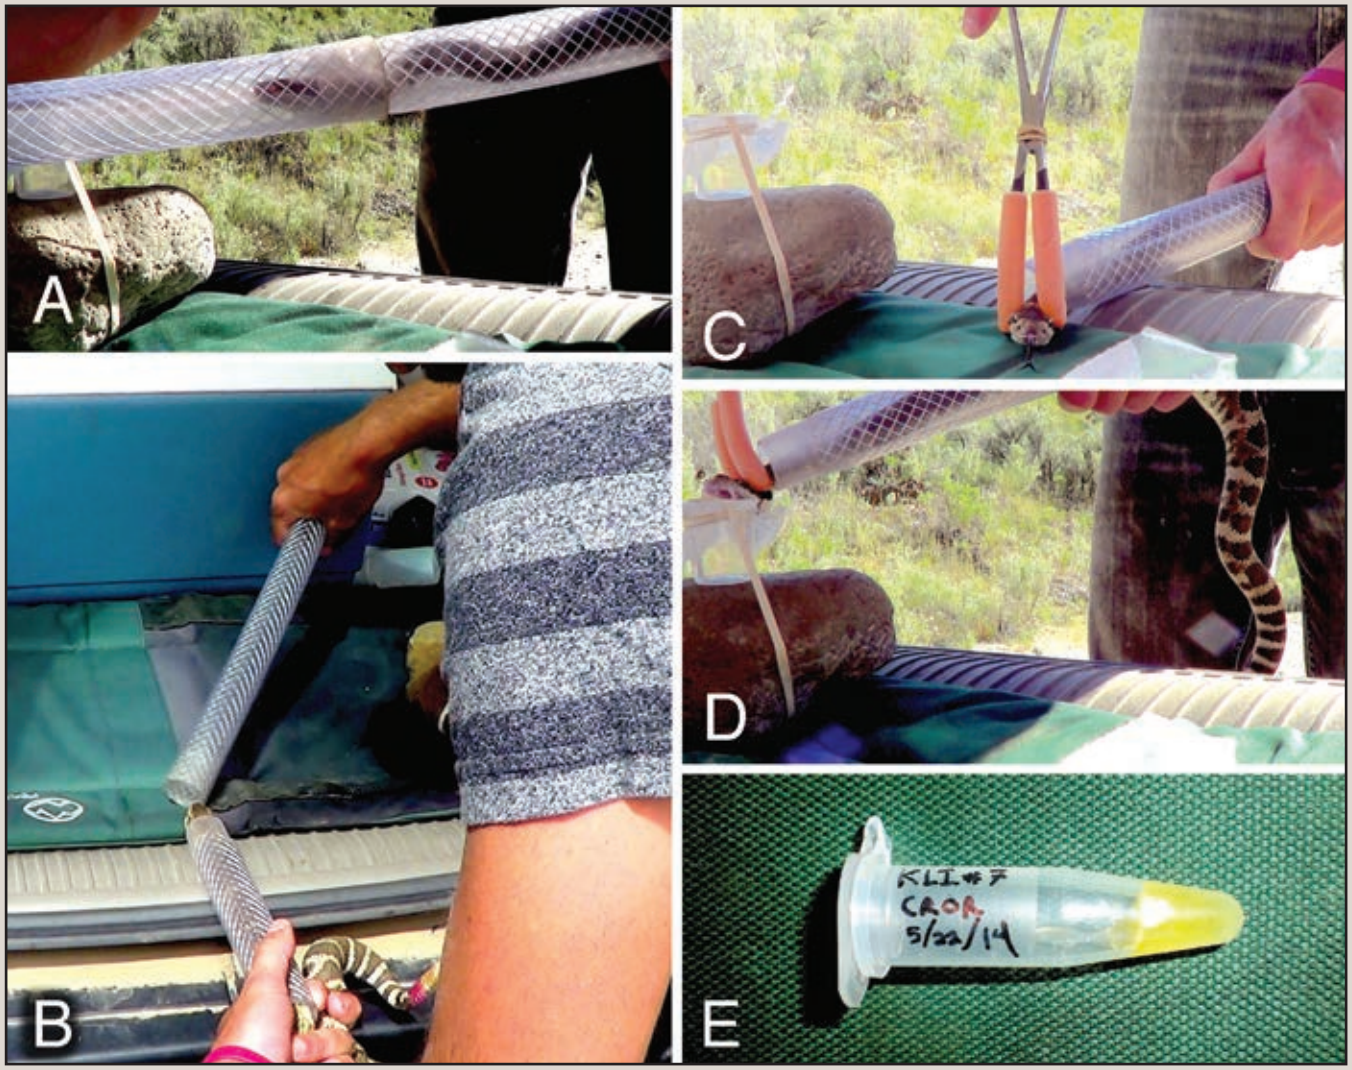

FIG. 3. The back of a research vehicle is one example of a field extraction station. A) Positioning an adult *Crotalus oreganus* in relation to the separation joint. B) Exposing head of an adult *Crotalus oreganus*. Proper hand placement is demonstrated during tube separation, i.e., grasping the break away section from the very end. Rattle painted pink to prevent re-capture. C, D) Application of the padded forceps. Establishing initial control of the head was particularly challenging at first. Patience and practice increased proficiency. E) Yield of approx. 0.2 ml from adult *Crotalus oreganus*.

(McCleary and Heard 2010). On multiple occasions, snakes were spotted on days following their venom extractions mirroring the behaviors observed during their capture (e.g., basking outside burrow, coiled in ambush).

The separating tubes revealed a few unexpected advantages during the field tests. First they were far more practical to carry around than standard snake tubes. Their ruggedness also provided an additional sense of security by eliminating the possibility of brittle tubes breaking with a snake in hand. Since they were made from vinyl and slightly malleable, the mistake of overshooting tube size for a given snake and having it turn around while tubed can be counteracted by simply squeezing the tube. In regard to applying for permits, this method merits the same or similar risk of envenomation as does general snake tubing. Since the process was designed to be implementation by a single individual, the risk of envenomation due to miscommunication is small. Most notably from a safety standpoint, there is no reason to rush during this method and the best results come from working slow and methodically. The extractor does not have to race or outwit the snake in pursuit of pinning or releasing it. This in turn reflects on the overall well being of the snake throughout this process; anyone familiar with snake handling can attest to the advantages of moving slow and methodical.

Areas of improvement also became apparent both in the field and during post-project discussions. The forceps used for gland manipulation might be further modified with the addition of elevated foam areas to provide more direct pressure to the glands. Alternatively, the gland manipulation step may be excluded altogether as the morphological consequences of this step are not yet completely understood (Giannotti et al. 2013). Inflammation of gland tissues may affect mRNA expression patterns and compromise transcriptomic analyses (D. Rokyta, pers. comm.). The snake tubes may be redesigned to increase control by positioning the separation point based on projected snake lengths for a given size tube (as opposed to making segments 30 mm and 70 mm, exclusively). Thus, smaller snakes may be held in relatively shorter tube segments than longer snakes during extractions. Another possibility is customizing the extraction opening with

a slightly smaller interior diameter at the separation point. This could further limit head contortions and increase overall control, although it may create issues when removing the snake afterwards. Material choice for the tubes might also be reconsidered for increased safety, control, and overall functionality of the joint.

I predict that given enough practice and (potential) equipment improvements, this technique will produce comparable yields to the traditional method at a greatly reduced risk of envenomation. Furthermore, the reduced risk supports general implementation of field extractions, which completely removes the step of bringing snakes into the lab. Collaborative efforts for improving and establishing a universally accepted technique will streamline safe venom research. Veterinary applications such as oral care for venomous snakes in husbandry settings might also benefit. Suggestions for improvements are encouraged. Video footage demonstrating the separating tube extraction technique may be viewed here:

Amphibians are underrepresented in the field of population genetics (Jehle and Arntzen 2002; Allendorf and Luikart 2007), and some groups, like those that breed in streams, are infrequently the focus of these studies (Emel and Storfer 2012). This is particularly true of dusky salamanders (genus *Desmognathus*), for which few, highly variable markers, such as microsatellites, have been published (e.g., Croshaw and Glenn 2003; Adams et al. 2005) or tested across multiple species within the genus (but see Munshi-South et al. 2013). Microsatellites loci are useful in characterizing patterns of gene flow and genetic diversity among populations (Avise 2004; Selkoe and Toonen 2006). There are multiple applications for such data within *Desmognathus*, a genus comprised of species that exhibit a wide range of ecologies (e.g., aquatic [*D. marmoratus*] to terrestrial [*D. aeneus*]) (Petranka 1998), that face a variety of threats, and among which hybridization is known to occur, or have occurred, in the recent past (Tilley 1988; Beamer and Lamb 2008).

The two species of *Desmognathus* of interest in this study are the Spotted Dusky Salamander (*D. conanti*) and the Southern Dusky Salamander (*D.* cf. *auriculatus*). *Desmognathus conanti* is a moderately sized, semi-aquatic species that was first described by Rossman (1958) from populations in western Kentucky and Tennessee. The expansive range of *D. conanti* stretches from western Kentucky south into the Gulf Coastal Plain and east across parts of the lower Atlantic Coastal Plain (Means and Bonett 2005). There are multiple genetically differentiated groups within *D. conanti* (i.e., Karlin and Guttman 1986; Bonett 2002; Kozak et al. 2005; Beamer and Lamb 2008), but whether these groups reflect strong phylogeographic structure or distinct species has yet to be determined. Populations appear stable throughout most of the aforementioned range, but this salamander is classified as "critically imperiled" (state rank S1) in Arkansas, "imperiled" in Illinois (S2), and "vulnerable" in Kentucky (S3) (NatureServe 2015). These salamanders can be found in seeps, springs, and lower order streams in areas with moderate relief, as well as along the edges of swamps and floodplain pools or sloughs (Valentine 1963; Means 2005a; Jensen et al. 2008; Graham et al. 2010).

Molecular work completed by Beamer and Lamb (2008) indicates that what is currently referred to as the Southern Dusky Salamander (*Desmognathus auriculatus*) is likely a conglomeration of several species. The original range of *D. auriculatus* stretched along the Coastal Plain from eastern Texas in to Virginia and included a large portion of both Louisiana and Mississippi (Means 2005b). Populations from Louisiana and Mississippi attributed to *D. auriculatus* were not included in Beamer and Lamb's (2008) work, and, pending taxonomic revisions, we will refer to these populations as *D.* cf. *auriculatus*. *Desmognathus* cf. *auriculatus* is infrequently encountered in Louisiana and Mississippi. It is classified as "critically imperiled" (state rank S1) in Louisiana (Louisiana Natural Heritage Program 2015; and see Boundy [2005]) and as "rare or uncommon" to "imperiled" (S2S3) in Mississippi (Mississippi Natural Heritage Program 2015). In Louisiana and Mississippi, *D.* cf. *auriculatus* is associated with swamps and bottomland seeps and streams that contain black-organic or silt/clay-based muddy substrates.

Methods and Results

Tissue samples from *Desmognathus* species were collected from various locales in Mississippi. We used sharp scissors sterilized with ethanol, by flame, or both to collect 2–5 millimeters of tissue from the tip of the tail. Tail tips were placed in individually labeled vials containing 95% ethanol and stored at –20°C in the laboratory. Total genomic DNA was extracted with the DNeasy Tissue Kit (QIAGEN Inc.). We sent genomic DNA for a specimen of *D. conanti* from south Mississippi to the Savannah River Ecology Laboratory Molecular Ecology Laboratory (SREL MEL), where an Illumina paired-end shotgun library was prepared (Nunziata et al. 2013) and PAL_FINDER_v0.02.03 (Castoe et al. 2012) was used to extract reads containing di-, tri-, tetra-, penta-, and hexanucleotide microsatellite sequences. SREL MEL used Primer3 (Rozen and Skaletsky 2000) to design primers for these reads. We screened 40 of the 4777 loci identified by SREL MEL. These included tetra- and pentanucleotide loci for which sequences occurred only one or two times among reads.

We collected tissue from two, widely separated populations of *D. conanti* from Mississippi. The northernmost population occurs on private-property in a seep-fed, 1st order (Strahler 1964) stream feeding into the Yazoo River in Union Co. (N = 23; population A), and was accessed with permission from the property owners. All individuals from this population were collected on 5 August 2014. The southernmost population of *D. conanti* is ca. 300 miles south at the Ward Bayou Wildlife Management Area in Jackson Co., Mississippi (N = 30; population B). Salamanders were caught in and along small seeps draining into a 1st order stream. Tissue samples were collected from this population from January to April 2013. We collected tissue from a single population of *D.* cf. *auriculatus* from the floodplain of a 2nd order stream in Camp Shelby, Forrest Co., Mississippi (N = 23) on two separate occasions, 27 October 2014 and 27 February

TABLE 1. Characterization of 20 polymorphic microsatellite loci developed for *Desmognathus conanti* and tested with *D.* cf. *auriculatus*. Forward primers are reported without the tailed M13 sequence. The information for each locus is reported such that the first row contains information for a population of *D. conanti* from Union Co., Mississippi (A), the second for a population of *D. conanti* from Jackson Co., Missouri (B), and the third row for a population of *D.* cf. *auriculatus* from Forrest Co., Missouri (cf. auric.). All loci were tested on 23 individuals for A, 30 individuals for B, and 23 individuals for cf. auric. Size describes the range of observed alleles in base pairs not including the 19 base pairs from the M13 tail. N indicates the number of individuals successfully genotyped, and NA the number of alleles. HO and HE are observed and expected heterozygosities, respectively. T°C represents the annealing temperature used for that population and locus.

‡Locus deviates significantly from HWE after Bonferroni correction across loci for that population. †Locus was optimized with 3 mM concentration of MgCl2 for the population in question. All loci for population A were amplified using 1 µL of genomic DNA. Loci that were not successfully or reliably amplified for one population are indicated with a –.

2015, to test for cross-species amplification of these primers. All individuals were captured by hand from beneath natural cover items (e.g., litter packs, logs), and we released any individuals that we did not use as site vouchers immediately following tissue collection. Species identifications were verified by amplifying and sequencing a ~550 base pair region of the mitochondrial gene cytochorome oxidase subunit c (*cox1*) using primers from Beamer and Lamb (2008) and the Eurofins sequencing service (unpublished data).

We used five individuals of *D. conanti* from population B and five individuals of *D.* cf. *auriculatus* from the Camp Shelby population to complete our initial screening of the 40 loci meeting our selection criteria. Amplifications were conducted in a total volume of 12.5 µl using 1X standard Taq (Mg-free) buffer (BioLabs), 2 mM dNTPs, 2 mM $MgCl_2$, 0.1875 units of *Taq* polymerase (New England Biolabs), 0.3 µM of the M13 tailed forward primer (Boutin-Ganache et al. 2001), 0.3 µM of the reverse primer, 0.004 µM of the labeled M13 primer (LICOR Co.), 20–150 ng of template DNA, and water to the final volume. PCR cycling conditions consisted of an initial denaturing step of 94°C for 2 min followed by 35 cycles of 30 sec at 94°C, 30 sec at 56°C, and 1 min at 72°C. A final elongation step of 10 min at 72°C ended the cycle. We visualized microsatellite alleles on acrylamide gels using a LICOR 4300 DNA analyzer, and sized alleles using GeneProfiler ver. 4.05 (LICOR Co.). Any loci that amplified well under these initial conditions were then screened for polymorphism across all individuals in each of the three populations. We attempted to optimize conditions for loci that did not initially amplify, or for which bands were too faint to score, by using one or more of the following variations: decreasing the annealing temperature to 54 or 52°C, increasing the concentration of $MgCl_2$ to 3 mM, or increasing the amount of DNA template used. Annealing temperatures and conditions for 20 polymorphic loci are reported in Table 1. We calculated summary statistics for these loci for each population using GENALEX 6.5 (Peakall and Smouse 2012), and tested for deviations from Hardy-Weinberg equilibrium and for linkage disequilibrium using the probability tests in GENEPOP v 4.2 (Raymond and Rousset 1995; Rousset 2008). We adjusted our threshold for statistical significance for all multiple tests within a population using sequential Bonferroni procedures (Rice 1989).

A total of 20 loci were optimized across the species and populations tested. Sixteen loci amplified reliably for population A, 19 for population B, and 11 for the single population of *D.* cf. *auriculatus* (Table 1). For population A, the number of alleles per locus ranged from 1 to 17 (mean = 8.50), and observed heterozygosity levels from 0.000 to 0.900 (mean = 0.627). Individuals screened from this population had only 2 alleles for *Dcon01,* and only one allele for both *Dcon28* and *Dcon38.* No loci deviated significantly from Hardy-Weinberg Equilibrium (Table 1). For population B, the number of alleles per locus ranged from 5 to 19 (mean = 11), and observed heterozygosity levels from 0.364 to 0.923 (mean = 0.721). Four loci, *Dcon13, Dcon17, Dcon34,* and *Dcon38,* deviated significantly from Hardy-Weinberg Equilibrium (Table 1). For the population of *D.* cf. *auriculatus,* the number of alleles per locus ranged from 1 to 9 (mean = 4.27), and observed heterozygosity levels from 0.000 to 0.750 (mean = 0.401). Individuals screened from this population had only 2 alleles for *Dcon11, Dcon21,* and *Dcon23,* and only one allele for *Dcon28.* Three loci, *Dcon13, Dcon26,* and *Dcon34* deviated significantly from Hardy-Weinberg Equilibrium (Table 1). No loci exhibited linkage disequilibrium in any of the species or populations tested.

Discussion

The long-term survival of amphibian species and the preservation of regional biodiversity will depend on our ability to identify current and historic patterns of population connectivity (i.e., gene flow) and genetic diversity using molecular tools, such as these 20 microsatellite loci (Semlitsch 2002; Beebee 2005; Allentoft and O'Brien 2010). Genetic diversity is positively correlated with fitness in many amphibians (Allentoft and O'Brien 2010) and it can buffer populations against stressors such as UV-B radiation (Weyrauch and Grubb 2006) and

emergent pathogens (Pearman and Garner 2005). Population connectivity, which counteracts inbreeding depression and genetic drift, is one facet responsible for maintaining high levels of genetic diversity (Allendorf and Luikart 2007). Consequently, it is important to understand how gene flow is affected by prior and ongoing management practices and the natural history of the species of interest. We successfully amplified many of these microsatellite loci in both of our study species (*D. conanti* and *D.* cf. *auriculatus*), as well as in widely separated populations within one of these species (e.g., population A and B of *D. conanti*). This is, hopefully, indicative of the utility of these loci in addressing the aforementioned areas of conservation interest not only across populations of *D. conanti* and *D.* cf. *auriculatus*, but also across other species within the genus *Desmognathus*. Our laboratory is currently using these microsatellites in tandem with mitochondrial gene sequencing to characterize geographic patterns of genetic structure in *D. conanti* across the Gulf Coastal Plain, as well as to examine fine-scale patterns of gene flow within the Pascagoula and Pearl River Drainages. Future endeavors include using these loci to examine current levels of genetic diversity and isolation in Mississippi populations of *D.* cf. *auriculatus*, as well as to investigate the paternity of clutches of eggs that have resulted from captive courtship trials for this species (unpublished data).

Acknowledgments.—This work was funded by the following grants to JYL: a National Science Foundation (NSF) Graduate Research Fellowship under Grant #0940712, an NSF "Molecules to Muscles" GK-12 Fellowship Award #0947944 through the University of Southern Mississippi, and a 2014 grant from the Chicago Herpetological Society. We thank Rochelle Beasley and Stacey Lance (University of Georgia) for Illumina sequencing and processing of reads. We thank James R. Lee (The Nature Conservancy), Lynn McCoy, and Kathy Shelton (Mississippi Department of Wildlife, Fisheries and Parks) for their help in locating collection sites. We would also like to thank a number of individuals for their help in the field, including Grover J. Brown III, Cybil C. Huntzinger, James R. Lee, Kevin Narum, Abby Sinclair, and students from the 2013 USM Herpetology class. Further, we are grateful for pertinent insights provided by D. Bruce Means, Joseph Bernardo, and David A. Beamer, and for Brandon C. Morris' editorial assistance. Scientific collection permits were provided by the Mississippi Department of Wildlife, Fisheries and Parks. All work was conducted in accordance with the appropriate institutional Animal Care guidelines.

Lateral Vessel Puncture: A New Method for Drawing Blood from Small Snakes

Genetic analyses have revolutionized our understanding of phylogenetic relationships (Pyron et al. 2013), interactions between and within populations (Castoe et al. 2007), relationships between species, geology, and climate (Ornelas et al. 2013), and other important aspects of biology (Vonk et al. 2013). Increasingly, they are the preferred method for answering questions not only regarding the evolution of organisms, but also their conservation (Holycross and Douglas 2007). However, obtaining reliable genetic material from some organisms in the field without injuring or sacrificing the animal can be challenging.

Researchers requiring a non-lethal method of collecting genetic material from small snakes often use ventral scale clips (e.g., Bryson et al. 2011). The keratin cells that comprise the posterior portion of each scale are non-nucleated, so scale clips must include connective tissue at the base of the scales (Burbrink and Castoe 2009). Biologists have long used ventral scale clips to mark snakes in population studies (Woodbury 1956). Negative effects have not been reported, but infection is a potential risk, especially given that the resulting open wound remains in direct contact with the ground.

Although scale clips can provide useable amounts of DNA, blood is a more reliable source of non-degraded genetic material. The primary method used by herpetologists to draw blood from snakes is venipuncture of the caudal vein (Gorzula et al. 1976). The methodology involves using a syringe to puncture the tail from the ventral side through to the vertebral column, whereupon the needle punctures the caudal vein and blood can be drawn. While some biologists have had success using this technique with relatively small snakes (e.g., Holycross and Douglas 2007), I found that the technique rarely worked in a study of *Crotalus pricei* (Twin-spotted Rattlesnakes), one of the smallest rattlesnakes. Not only did I typically fail to obtain blood, but the method involved an apparent risk of damage to the snake's hemipenes, hemipene retractor muscles, musk glands, and spinal cord. I did not observe any injuries caused by this method, but it is likely that harm to the animal would be subtle and go unnoticed.

FIG. 3. Puncture the blood vessel with a syringe and draw the drops of blood that form on the surface.

In order to obtain genetic material while mitigating the risks these techniques may present to the snake, I developed a new blood draw method that combines clipping scales and puncturing a blood vessel. First, orient the snake in a vertical or near-vertical position so that its head is elevated, causing blood to pool in the tail. This is easiest to achieve if the snake is tubed (Murphy 1971). The snake should remain in this position throughout the blood-drawing process. A pair of cuticle clippers and a small area on one side of the snake's tail should be cleaned with 70% isopropyl alcohol or another disinfectant. Then, create a skin flap on the cleaned side of the tail with the cuticle clippers (Fig. 1). A skin flap can be made by slightly angling the cuticle clippers to ensure that there is no skin between the lowest ends of the blades while there is skin between the upper ends. The incision should be about 2 mm wide and should extend from about 1 mm below the dorsal-ventral scale boundary up through the second dorsal scale row (Fig. 2). The incision should be made at the point where you can cover this entire area in a single clip. This point will be closer to the vent in smaller snakes and closer to the tail tip in larger snakes. Leave the skin flap attached on the dorsal side. Care must be taken to cut only the skin and not any underlying tissue.

Fold the skin flap up with a sterile syringe needle. This exposes a small blood vessel which is generally located near the dorsal-ventral interface line, but is embedded in muscle and can change position to be as much as two dorsal scales above that line or a bit below. This thin red blood vessel is clearly visible against the gray exposed tissue. Puncture the vessel with the syringe needle and then remove the needle. I use 25-gauge needles but other sizes may work equally well. If successful, drops of blood will form at the puncture site within 30 seconds. Draw each blood drop into the syringe and deposit it in a vial containing preservative (Fig. 3).

I have found that even a single drop of blood is sufficient for obtaining enough genetic material for analysis, but typically draw three to five drops of blood to ensure that there is plenty of material. When enough blood has been obtained, reorient the snake so that the tail is elevated, causing blood to flow toward the head. This often stops the bleeding if it has not stopped already. Fold the skin flap back over the wound with the syringe needle and use a paper towel or sterile pad to apply direct pressure to the wound until you are certain that bleeding has completely stopped. Direct pressure will usually stop any bleeding within 30 seconds, though occasionally several minutes of direct pressure may be needed. Finally, apply a skin sealant to the wound to help keep the skin flap in place and reduce the risk of infection. I use Skin Shield® Liquid Bandage (Del Pharmaceuticals, Inc., Uniondale, New York), but other skin sealants such as Vetbond™ Tissue Adhesive (3M, Saint Paul, Minnesota) should work as well.

Although DNA lysis buffer is typically recommended as the preferred field preservative for genetic samples (Burbrink and Castoe 2009), I recommend using 70–95% ethanol with this blood draw method. The blood drops from the punctured vessel usually form slowly and single drops of blood dry quickly in the syringe needle, so in most cases it is necessary to flush the blood out of the syringe with the preservative during the blood collection process. This leaves trace amounts of preservative on the syringe needle which could enter the snake's bloodstream. While many of us have found through personal experience that small amounts of ethanol do not have lasting negative effects, the chemicals in DNA lysis buffer may or may not be harmful.

I have attempted to use this lateral vessel puncture method to draw blood from 100 *Crotalus pricei*. Although there have been a few occasions when I was unable to get snakes to bleed, my success rate is 92%. I have successfully drawn blood from snakes ranging in size from 161 mm SVL, 3.5 g to 551 mm SVL, 126 g. This method is a bit easier to employ if one person holds the snake while the other draws the blood, but it is not difficult to conduct the entire operation alone in the field as long as all materials are ready and at hand.

The main advantage to the lateral vessel puncture method over the traditional caudal vein venipuncture method is that it can be used with small snakes in which the caudal vein is too narrow for success to be likely. An additional advantage is that all injuries can be observed clearly and mitigated with basic first aid techniques (elevation and direct pressure). The disadvantage is that in most cases only a few drops of blood can be collected before the snake stops bleeding. However, a few drops of blood should be sufficient for any genetic analysis.

The lateral vessel puncture method has proved to be successful with a small, terrestrial rattlesnake species and should work equally well for other terrestrial snake species. The method was especially successful with the smallest snakes, as blood was obtained during all attempts with snakes measuring 161–320 mm SVL (N = 22). Researchers studying snakes that are significantly

smaller than *Crotalus pricei* (e.g., *Tantilla*) may find this method useful. However, the method may prove to be less effective with arboreal species. Arboreal snakes can regulate the blood flow to their tails very effectively while in a vertical orientation, which may mean that less blood would be produced by a lateral vessel puncture (Lillywhite 1987).

Acknowledgments.—I thank Mike Schroff for his assistance and encouragement in developing this technique, Matt Kaplan for helping me determine whether my efforts were in vain, Julio Lemos Espinal for facilitating work conducted in Mexico, Bruce Weise for some of the accompanying photos, and Kevin Bonine, Raul Diaz, Matthew Murdoch, and Alexandra Sumarli for helpful comments on this manuscript. All snake captures, handling, and blood draws were conducted under Arizona Game and Fish Department Scientific Collecting Permits or SEMARNAT permit SGPA/DGVS/07302/14 (in Mexico). This work was done independently so there was no IACUC review, but all procedures followed standard guidelines and consisted of actions routinely approved by IACUC boards.

A key derived feature of amphibians is their unique skin morphology, which includes a perpetually moist surface associated with mucous and granular (e.g., poison) glands (Duellman and Trueb 1986). The skin morphology of different amphibian species varies considerably (Heatwole and Barthalmus 1994), ranging from the highly toxic alkaloids sequestered onto the surface of dendrobatid frogs (Saporito et al. 2004) to the highly vascularized surface of the lungless plethodontid salamanders (Czopek 1962). Associated with this diversity of skin morphologies is an array of microorganisms, which when mutually beneficial, represent an important line of defense against pathogens (Belden and Harris 2007; Ramsey et al. 2010). The moist, thin, bare surface of amphibian skin allows gas exchange and is permeable to water (Heatwole and Barthalmus 1994), and therefore could be less effective at preventing pathogen transmission than the more impervious skin surfaces of other tetrapods. In addition, the skin of amphibians has been documented in the past to have a poor or non-existent cell-mediated and humoral immune response (Berger et al. 1998; Pessier et al. 1999; Woodhams et al. 2006). Recent evidence indicates that amphibians can acquire behavioral and immunological resistance to emerging fungal pathogens like *Batrachochytrium dendrobatidis* (McMahon et al. 2014). Amphibians have also developed an armory of potent antimicrobial peptides (Nicolas and Mor 1995; Simmaco et al. 1998; Rollins-Smith et al. 2002) that may somewhat compensate for their lack of scales, feathers, and hair. Evidence suggests

Table 1. Standardized washing protocol developed and tested in this study.

Protocol Step	Researcher #1 Description	Researcher #2 Description
Squirt bottle	Begin the protocol with clean nitrile or latex gloves. Hold the salamander while researcher #2 washes it.	Wash the salamander for 15 seconds (25 mL sterile ddH_2O) using a squirt bottle.
Wash bath #1	Change into fresh gloves at this time to prepare for transfer of the salamander into the second wash bath after the first wash is complete.	Place the salamander into a sterile 90 mm petri dish containing 25 mL sterile ddH_2O and swirl the plate in a circular motion for 30 seconds.
Wash bath #2	Wearing fresh gloves, place the salamander into a sterile 90 mm petri dish containing 25 mL sterile ddH_2O and swirl the plate in a circular motion for 30 seconds.	Change into fresh gloves at this time to prepare for transfer of the salamander into the third wash bath after the second wash is complete.
Wash bath #3	Change into fresh gloves at this time to prepare for swabbing of the salamander.	Wearing fresh gloves, place the salamander into a sterile 90 mm petri dish containing 25 mL sterile ddH_2O and swirl the plate in a circular motion for 30 seconds.
Swabbing	Hold the salamander while researcher #2 performs the swabbing technique.	Swab the salamander on the left, right, dorsal, and ventral sides for a total of 15 strokes from the head to the tip of the tail.
Storage	Store swabs at -20°C within one hour of being collected for lab specimens or in 99.9% acetone for field collections.	

that the cutaneous antimicrobial peptides and microbiota associated with amphibians may play a key role in maintaining amphibian health and mediating the effects of emerging infectious diseases, which have been implicated as a major cause of amphibian declines worldwide. For example, species-specific differences in both antimicrobial peptides (Rollins-Smith et al. 2002; Rollins-Smith 2009) and microbiota (Harris et al. 2009) are associated with susceptibility to *B. dendrobatidis*, the fungal pathogen responsible for amphibian population crashes in Australia, western North America, and the American tropics. Specifically, cutaneous microbiota and secreted antimicrobial peptides of amphibians can kill or inhibit the growth of *B. dendrobatidis* (Rollins-Smith and Conlon 2005; Harris et al. 2006; Brucker et al. 2008a; Brucker et al. 2008b; Becker et al. 2009; Harris et al. 2009). Therefore, a better understanding of amphibian microbial communities may increase our understanding of this devastating wildlife disease.

To date, studies on the skin microbiota of amphibians have been variable, with protocols differing substantially among studies. For example, the two most cited papers (Culp et al. 2007; Lauer et al. 2007) describing the methodology for removing environmental microbes prior to skin sampling and characterization of the resident microbial communities differ in methodology (e.g., the number of times each animal was washed and the volume of water used for each wash). However, these two protocols are often cited in a single study, and citing studies do not precisely follow the same protocols (McKenzie et al. 2012; Fitzpatrick and Allison 2014; Kueneman et al. 2014). A standardized washing protocol is necessary to allow for comparison of independent studies on the skin microbiota of amphibians.

Any conclusions regarding resident symbionts depend on the ability of the researcher to separate environmental microbiota from strict host/symbiont associations. To contribute to the study of amphibian skin microbiota, we set out to develop a standardized sampling protocol for biologists studying this topic. We conducted identical protocols using plethodontid salamanders in both the laboratory and the field, to ensure that this protocol can be used in both settings. Moreover, we used an experimental approach to determine if our washing protocol worked. We used a plate-based assay to count colony-forming units to show a sequential reduction of cultureable bacteria in our four-step protocol and molecular confirmation using PCR to show resident microbial community presence after the decontamination protocol. Here, we present evidence for our ability to retrieve microbial communities from amphibian skin after washing off transient environmental microbes.

Materials and Methods

Study species.—Red-backed Salamanders (*Plethodon cinereus*; N = 23) were collected at Jolliffe Nursery in Wetzel Co., West Virginia, USA (39.657°N, 80.555°W), on 20 December 2013. Red-backed Salamanders were kept individually in microcosms (40 × 25 × 18 cm) on natural soil substrate (depth = 10 cm), misted daily with water, and maintained at 21.5°C on a 12 h dark: 12 h light cycle in the laboratory (as a component of another research project). After 12 weeks salamanders were subjected to the washing protocol described below. The washing protocol was also field tested on Northern Gray-cheeked Salamanders (*Plethodon montanus*; N = 6) in Nantahala National Forest (35.700°N, 082.399°W), North Carolina, USA. Northern Gray-cheeked Salamanders were collected by hand from beneath logs on 12 May 2014, stored with moist substrate in plastic ziplock bags, and subjected to the washing protocol within 8 h of collection.

Washing protocol.—This procedure required two researchers beginning the protocol with clean nitrile or latex gloves and is outlined in Table 1. Researcher #1 held the amphibian while

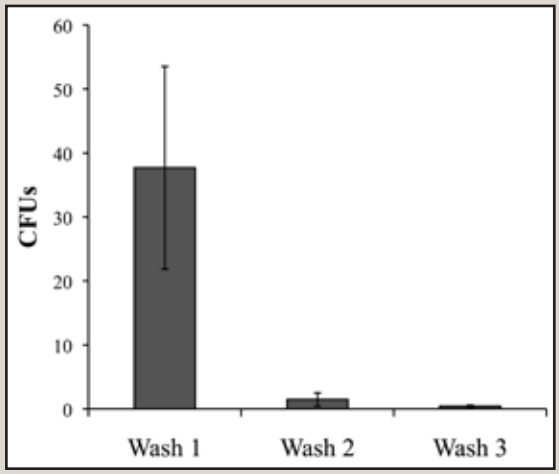

FIG. 1. Colony forming units (CFUs) for three sequential washes of Red-backed Salamanders (*Plethodon cinereus*). Mean (± 1 S.E.) CFUs.

FIG. 2. Gel electrophoresis of laboratory-tested Red-backed Salamander (*Plethodon cinereus*) skin swabs (lanes 1–10) and negative controls (–a, –b).

FIG. 3. Gel electrophoresis of field-tested Northern Gray-cheeked Salamanders (*Plethodon montanus*) skin swabs (lanes 1–6) and negative control (lane –a).

researcher #2 washed the animal for 15 sec (25 ml sterile ddH_2O) with a squirt bottle. The animal was then placed into a sterile 90 mm Petri dish with 25 ml sterile ddH_2O and gently swirled in a circular motion for 30 sec. With a new set of gloves researcher #1 picked up the animal and carried out two additional (sequential) Petri dish washes repeating the aforementioned steps. The squirt bottle was only used once at the beginning of the protocol. With a fresh set of gloves, researcher #1 then picked up the animal while researcher #2 swabbed it 15 times on the right, left, dorsal, and ventral sides of the salamander. A total 15 strokes with the swab was performed from the head to tail tip of each salamander. Swabs were stored at -20°C within one hour of being collected (Red-backed Salamanders) or stored in 99.9% acetone (Fukatsu 1999) for field collections (Northern Gray-cheeked Salamanders); differences in storage conditions allowed assessment of the feasibility of field *vs* lab-based applications of this protocol.

Plate-based assay.—An aliquot of the Petri dish water from the three sequential salamander washes was sampled using a plate-based method by quantifying bacterial colony forming units (CFUs). Specifically, 150 µl of wash water was transferred to a 90 mm Tryptic Soy Agar (Fisher Scientific) plate and spread across the surface of the medium using a glass L-shaped rod. Plates were then inverted and incubated for 48 h at 32°C. CFUs were counted and recorded for each of the three sequential washes. To evaluate whether our washing protocol reduced the quantity of bacteria on the salamander's skin we performed a repeated measures ANOVA on ln-transformed CFUs using JMP Pro 9.0.0.

Molecular methods.—To confirm the presence of resident microbial communities a subset of the salamanders (N = 10, *P. cinereus*; N = 6, *P. montanus*) subjected to the washing protocol were swabbed with a sterile cotton swab autoclaved for two hours (Gefrides et al. 2010) and DNA extracted with the Qiagen DNA Micro Kit according to the manufacturers protocol for isolating genomic DNA from small volumes of blood. The following alterations were made to the DNA extraction protocol: extraction was performed directly from the swab after an incubation period of 7 h (with proteinase K - step 5 of protocol). PCR conditions were as follows for a 25 µl reaction: 12.5 µl New England Biolabs Taq 2X Master Mix, 1 µl (10 µM) forward primer 515F, 1 µl (10 µM) reverse primer 806R (Caporaso et al. 2011), 5 µl DNA, 5.5 µl sterile ddH_2O. Electrophoresis was performed in a 1% agarose gel at 140 volts for 40 min. Five µl of each PCR reaction was added to each well. PCR amplicon fluorescence was interpreted as the presence of resident microbial communities from the salamander skin.

RESULTS

There was a significant reduction in the amount of environmental bacteria (CFUs) with washing ($F_{1,45} = 34.89$; $P < 0.0001$; Fig. 1). DNA extraction, PCR, and gel electrophoresis of both field and lab tested skin swabs indicated the presence of PCR amplicons targeting resident bacterial communities on the skin of these salamanders (Figs. 2– 3). For *P. cinereus*, 9 of 10 skin swabs showed PCR amplicons (Fig. 2), whereas for *P. montanus* 4 of 6 skin swabs had dull PCR amplicons (Fig. 3).

DISCUSSION

This study successfully demonstrates and tests a new standardized protocol for removing environmental microbes for studies on resident microbes composing the amphibian microbiome. We show that successive washes with sterile ddH_2O significantly reduce the amount of CFUs and also that PCR amplifiable microbial DNA is present upon concluding the protocol from salamanders in both the field and the laboratory. Field and laboratory experiments revealed similar results, confirming that our methods can be made portable for biodiversity inventories. Presumably, since no significant change was detected after the third wash in either laboratory maintained or field-collected salamanders, only the endemic microbiota associated with the salamander is sampled after our protocol. This technique is similar to previous studies that showed similar results (Lauer et al. 2007). This protocol will help standardize wash time, water volume, and researcher technique, all of which are critical in the removal of environmental microbes from amphibian skin. Adopting a standardized protocol amongst labs will be imperative for direct comparison of future studies on the amphibian microbiome.

TABLE 2. Comparison of washing protocols.

	Study species	Number of washes	Total wash time (sec)	Total wash water volume (ml)	Type of wash	Swabbing protocol
This study	*Plethodon cinereus* *Plethodon montanus* *Notophthalamus viridescens* *Lithobates catesbeianus*	4	105	100	sterile ddH_2O	15 swab strokes from head to tail on the right, left, dorsal, and ventral sides
Culp et al. 2007	*Plethodon cinereus*	3	90	60	sterile ddH_2O	Dorsal and ventral sides swabbed; number of strokes unreported
Lauer et al. 2007	*Plethodon cinereus*	2	Not reported	50	sterile dechlorinated H_2O	10 swab strokes on lateral and ventral sides
McKenzie et al. 2012	*Lithobates pipiens* *Pseudacris triseriata* *Ambystoma tigrinum*	3	Not reported	300	sterile H_2O	Swab brushed over entire amphibian for 30 sec
Fitzpatrick & Allison 2014	*Plethodon jordani*	1	Not reported	50	sterile dechlorinated H_2O	10 swab strokes on lateral and ventral sides
Kueneman et al. 2014	*Anaxyrus boreas* *Pseudacris regilla* *Taricha torosa* *Lithobates catesbeianus* *Rana cascadae*	2	Not reported	100	sterile H_2O	Swab brushed over ventral surface and limbs for 30 sec
Walke et al. 2014	*Lithobates catesbeianus* *Notophthalmus viridescens*	2	Not reported	Not reported	sterile dechlorinated H_2O	10 swab strokes along the ventral and 5 strokes along each dorsal/lateral sides

We acknowledge that a plate-based assay is a limitation of this study since it only quantifies microbes capable of growing on synthetic medium at 32°C. In addition, gel electrophoresis of PCR amplicons from salamander skin swabs was used to confirm the presence of skin symbionts. It could be argued that these microbes are environmental in origin. However, based on past research by Culp et al. (2007), Lauer et al. (2007), and the plate-based assay results in this study, we conclude that environmental microbes were successfully removed and the PCR amplicons are representative of skin symbionts of *P. cinereus* and *P. montanus*. We also acknowledge the limitations placed on this washing protocol by the size of the amphibian; studies on larger amphibians will be restricted by Petri dish size. This protocol was designed for small to medium amphibians (< 150 mm length × < 15 mm height) and should prove useful for studies of many similar-sized amphibian species worldwide.

Previous studies have reduced cutaneous microbiota using broad-spectrum antibiotics and/or hydrogen peroxide in salamanders and fish (Lumsden et al. 1998; Russo et al. 2007; Becker and Harris 2010). Our study suggested that these extreme measures might not be necessary to remove environmental microbes. We hypothesize that a volume of 50 ml of sterile water is sufficient to remove the vast majority of environmental microbes, similar to that used in previous studies (60 ml ddH_2O in Culp et al. 2007; 50 ml ddH_2O in Lauer et al. 2007). If this is the case, then results based on next-generation sequencing studies using variations on these washing protocols are likely accurate in the characterization of the amphibian skin microbiome (McKenzie et al. 2012; Fitzpatrick and Allison 2014; Kueneman et al. 2014; Walke et al. 2014).

The need for standardization of such protocols has arisen due to the precarious health of world amphibian populations. This is due in part to emerging infectious pathogens such as *B. dendrobatidis* and the newly discovered *B. salamandrivorans*, which has caused population crashes of salamanders in Europe and has the potential to cause worldwide declines if it spreads to North America and Asia (Martel et al. 2013). Since the associated microbiota of amphibians can be considered an important component of the amphibian immune response, studies focusing on intra- and interspecific differences in microbiota components and diversity are needed to better understand interactions between the skin of amphibians and pathogens. In the future such studies are capable of becoming exceedingly sophisticated with the advent of next-generation sequencing and bioinformatics approaches. However, a necessary first step is a clean sample. We recommend standardization of protocols as studies proceed. This protocol provides researchers with a viable and experimentally tested washing protocol to remove environmental bacteria from the skin of small to medium sized amphibians.

Acknowledgments.—Salamanders were collected under permit numbers: CHE901200, 14-SC00873. DMW would like to thank Nancy Jolliffe and Bob Schlegel at Jolliffe Nursery at Knob Creek for allowing this research project to take place on their property, and Benjamin Bennett for coordinating the research efforts. DMW would also like to thank the students from his Introduction to Research classes (2013–2015) at The University of Findlay for their contribution to this project and Adam E. Rakestraw, Natalie E. Rakestraw, and Madelyn R. Rakestraw for aiding in the collection of numerous specimens. The University of Findlay's institutional research policies and guidelines for the ethical treatment of animals were followed during this study.

AMPHIBIAN AND REPTILE DISEASES

This section offers a timely outlet for streamlined presentation of research exploring the geographic distribution, host range, and impact of emerging amphibian and reptile pathogens, especially fungal infections and ranaviruses. Amphibian chytrid fungi, *Batrachochytrium dendrobatidis* and *B. salamandrivorans* are both linked to amphibian mass mortality episodes, yet both have also been detected in amphibians without disease. Snake fungal infections in snakes and turtles are not well known, but are being detected more frequently in the last few years and may be primary or secondary infections leading to local losses. Ranaviruses also cause mass mortality, infecting both amphibians and reptiles, but have not yet been linked to large-scale declines. For each of these pathogens, we know relatively little about the global distribution, host range, or impacts on host populations. To improve our understanding of the scope of this issue, we encourage submission of studies that illuminate the geographic distribution, host ranges, and impact of these pathogens on amphibian and reptile populations, including research on individual species or groups of species, wild or captive animals, native or non-native species, live animals or museum specimens, environmental samples, and, provided there is sufficient sampling[1], reports of non-detections.

We ask authors to: 1) restrict the Introduction of their paper to a maximum of one paragraph to highlight the context of their study; 2) briefly include both field and laboratory Methods; 3) present Results in a Table, although a map might also be useful, and limited text; and 4) have a short discussion of a maximum of three paragraphs to touch upon key findings. Please include the following information in submissions as appropriate: coordinates and description of sampling areas (or please note if locations are extremely sensitive to reveal, and provide general area instead); species name(s) and life history stages examined, as well as other species present; whether samples were collected randomly or just from dead or moribund animals; date of specimen collection; evidence of unusual mortality; numbers of positive and negative samples; disposition of voucher specimens; name of collaborative laboratory or researcher conducting histological sections or PCR analyses; and names of cooperative land owners or land management agencies. We encourage researchers to conduct post-mortem examinations when possible to identify the cause of death when reporting mortalities. We aim to expedite the review and publication process! Please e-mail submissions directly to Associate Editor, Dr. Dede Olson.

Upon publication, we encourage authors to import their data to online disease reporting portals for rapid communication with researchers and natural resource managers. The Global Bd Mapping Project is available at: Bd-maps.net. The Global Ranavirus Reporting System is available at: https://mantle.io/grrs. The Bsal online portal is under construction at AmphibiaWeb.org.

[1]If a sample of 30 individuals of a particular life history stage of a particular species yields no positive results, and the diagnostic test is highly sensitive, one can conclude that the prevalence of infection is less than 10% with 95% confidence. With a sample of 10 an infection in one of four individuals could go undetected. We encourage researchers to collect sufficient samples so that negative results are meaningful.

Patagonia and other Andean regions of Argentina have many species of conservation concern because of local endemism or restricted regional distribution, and several threat factors including habitat alteration, chemical contamination, invasive species, and emerging diseases (Vaira et al. 2012). Since the first report of *Batrachochytrium dendrobatidis* (*Bd*) in Argentina in 2002, the pathogenic fungus has been reported in 14 of 23 provinces of the country, infecting numerous amphibian species in diverse environments (Herrera et al. 2005; Barrionuevo and Mangione 2006; Fox et al. 2006; Arellano et al. 2009; Ghirardi et al. 2009, 2012, 2014; Gutierrez et al. 2010; Delgado et al. 2012; Lescano et al. 2013). Many of these reports have addressed infection of endangered species inhabiting Andean regions, such as *Telmatobius atacamensis* and *T. pisanoi* in the northern Andes (Barrionuevo and Magione 2006) or *Alsodes pehuenche* and

FIG. 1. Study site on the Somuncurá Plateau (A) and the Laguna Azul (blue circle), Argentina. Collection site of *Atelognathus reverberii* individuals (star) on the banks of the Laguna Azul (B).

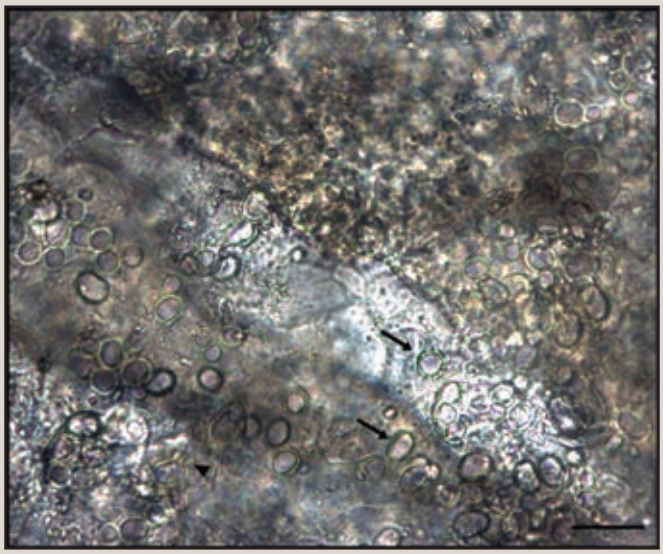

FIG. 2. Fresh skin surface (without stain) from the hind limbs of *Atelognathus reverberii* infected with *Batrachochytrium dendrobatidis* (400×) in Argentina. Arrows indicate zoosporangia and arrowhead a discharge tube. Scale bar = 20 µm.

Atelognathus patagonicus in the southern Andes (Fox et al. 2006; Ghirardi et al. 2014), with mortality recorded in the last species.

The Laguna Raimunda Frog, *Atelognathus reverberii* (Cei 1969), is an endemic species of conservation concern associated with permanent and temporary lagoons between 920 and 1200 m elevation in the Provinces of Chubut and Rio Negro (Cei 1969; Martinazzo et al. 2011). This frog, which has a fragmented distribution within its 500 km^2 range (Úbeda et al. 2004), is classified as Vulnerable in Argentina (Vaira et al. 2012) and is listed as Endangered by the IUCN Red List (Úbeda et al. 2004). The reproductive biology of the species is unknown, yet a relatively low reproductive potential is supported (Vaira et al. 2012). These attributes suggest that *A. reverberii* may be highly vulnerable to *Bd*-related population declines (see Bielby et al. 2008). Herein we provide the first report of the presence of *Bd* in *A. reverberii*, and associated mortality supporting a disease threat for this rare species.

In January 2015, during a field survey of this species in the Somuncurá Plateau, a Natural Protected Area of Río Negro Province, Argentina (41.288738°S, 66.831912°W; 1182 m elev.; Fig. 1), we found 11 dead *A. reverberii* individuals within a 0.6-m diameter and 1.5-m deep pit, holding 30-cm water in the bottom. These water pits, locally named "jagüeles," are dug by local residents near water bodies to obtain water for human and cattle consumption. The dead frogs were collected using latex rubber gloves (which were changed between specimens), and fixed in a solution of 10% formaldehyde. We analyzed shed skin from the hind limbs of all fixed individuals through direct examination without stain, under a compound optical microscope at 400× magnification. Specimens were deposited at the Colección Herpetológica del Museo de La Plata, Argentina (MLP A 5758–A 5768).

All dead individuals had excessive shed skin, which is one of the clinical signs of chytridiomycosis. We detected *Bd* zoosporangia in 100% (N = 11) of the shed skin samples analyzed (Fig. 2). Samples were compared with previous *Bd*-infected shed skin (Arellano, unpubl. data), some of which belonged to frogs in controlled *Bd* experimental infections with very high zoospore treatment doses (6×10^4 zoospore/ml). Due to the comparability of zoospore densities between these new and experimental skin samples, the natural infection of *A. reverberii* appeared to be very high. Based on previous studies of *Bd* in Argentina (Fox et al. 2006; Ghirardi et al. 2014; Bd-maps.net, accessed 2 June 2015), our detection of infection in *A. reverberii* is the southernmost record of *Bd* in this area of the central Patagonian steppe, and is near to the known southernmost extent of *Bd* in South America (in Chile, 43.78°S; Bourke et al. 2011).

In March 2015, we revisited the study area and found a high density of *A. reverberii* individuals (>100) hiding under rocks at the edge of Laguna Azul (the highest wetland of the area). A great number of individuals (~50%) were observed in a very weakened state and another ~10% were dead under the rocks, although these samples were not analyzed (Fig. 3).

The fact that we found dead and very weak individuals during the survey, added to the excessive shed skin seen in all the individuals, is very worrying, since this frog is potentially vulnerable to losses (Bielby et al. 2008) and is currently affected by several human-related activities. Other amphibian species on the Plateau, including *Pleurodema somuncuriensis*, an aquatic frog recently reported with *Bd* infection (Kacoliris, pers. comm.), are also listed as critically endangered (IUCN) (Úbeda and Lavilla 2004). Because many Argentinian regions remain unsurveyed for *Bd* and there are many endemic species or species with restricted distributions that are of significant concern (Vaira et al. 2012), much more extensive *Bd* sampling focused on these species is warranted to set priorities for future conservation actions.

FIG. 3. *Atelognathus reverberii* in Argentina. Appearance of a normal (left) and weakened (right) individual.

Acknowledgments.—This study was supported by the Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), PICT 2012. 0921, Conservation Leadership Programme (CLP), Conservation, Research and Educational Opportunities International (CREOI) and Rufford Foundation.

First Report of Ranavirus and *Batrachochytrium dendrobatidis* in Green Salamanders (*Aneides aeneus*) from Virginia, USA

The Green Salamander (*Aneides aeneus*) is distributed from extreme southwest Pennsylvania, USA to northern Alabama and Mississippi with a disjunct population in southern North Carolina, northeastern Georgia, and northern South Carolina (Petranka 1998). Because of unique habitat requirements, Green Salamanders are thought to be at risk of range-wide declines and extirpations (Corser 2001). Green Salamanders primarily dwell in rock crevices within rock outcrops (Gordon 1952; Rossell et al. 2009). Like its western congeners, Green Salamanders also inhabit arboreal habitats (Petranka 1998; Waldron and Humphries 2005) as well as decaying logs and stumps on the forest floor (Fowler 1947).

Green Salamander populations, especially those in the disjunct Carolina populations, have experienced declines and extirpations (Snyder 1991; Corser 2001). From the 1970s to 1980s local extirpations occurred in once-abundant North Carolina populations (Snyder 1991), and since the 1980s reductions of up to 98% have occurred in remaining populations (Corser 2001). One of the most-studied Blue Ridge escarpment populations was located at Biscuit Rock (Highlands, North Carolina; Gordon 1952; Snyder 1991; Corser 2001), and in the past five years this population became extirpated without a definitive cause (Lori Williams, unpubl. data). Various hypotheses have been proposed for Green Salamander declines such as disease and loss of surrounding timber (Snyder 1991; Petranka 1998; Corser 2001). Diseases are one of the leading causes of worldwide amphibian declines (Stuart et al. 2004; Young et al. 2004; Sodhi et al. 2008). Currently the Green Salamander is listed as threatened or endangered in Indiana, Maryland, Mississippi, North Carolina, Ohio, and Pennsylvania (MDNR 2005; MMNS 2005; PGCPBFC 2005; IDNR 2006; NCWRC 2014; ODNR 2014) and as a species of greatest conservation need in all other inhabited states (GDNR 2005; SCDNR 2005; TWRA 2005; VDGIF 2005; WFFDADCNR 2005; WVDNR 2005; KDFWR 2013). However, the potential impact of diseases on Green Salamanders is unknown, especially in Virginia.

Diseases caused by ranaviruses are responsible for amphibian die-offs throughout Europe and North America, including the southeastern United States (Green et al. 2002; Miller et al. 2011; Hoverman et al. 2012), and may contribute to population declines (Gray et al. 2009a). In the southern Appalachian Mountains, ranavirus infections have been reported in 18 species of plethodontid salamanders, but Green Salamanders have not been sampled (Miller et al. 2011; Hamed et al. 2013). Overall ranavirus prevalence in plethodontid salamanders has varied from 3–81% throughout the southern Appalachian Mountains (Gray et al. 2009b; Hamed et al. 2013) with salamanders from the genus *Desmognathus* having highest individual prevalence (Sutton et al. 2014). Only a single past study has sampled plethodontid salamanders for ranavirus within the Virginia portion of the Green Salamander's range (Wise Co.; Davidson and Chambers 2011a); overall ranavirus prevalence in this study was 33%, although Green Salamanders were not sampled.

Chytridiomycosis, the disease caused by *Batrachochytrium dendrobatidis* (*Bd*), has also been responsible for numerous amphibian declines and extirpations worldwide, especially in Central American anurans (Lips et al. 2006; Lötters et al. 2009). Infection rates of *Bd* vary throughout the southeastern U.S., with 17 species of plethodontid salamanders testing positive for *Bd* in past studies, and an additional 23 species not infected (Hughey et al. 2014). However, *Bd* is thought to have played a role in the declines of plethodontid salamanders in Central America and has been shown to be lethal to plethodontid salamanders in the western United States (Lips et al. 2006; Weinstein 2009; Cheng et al. 2011). Only a single prior study with a limited sampled size (N = 3) has surveyed Green Salamanders for *Bd*, with no positive results (Hill et al. 2011). Our goal was to determine ranavirus and *Bd* prevalence in Green Salamander populations from southwest Virginia.

To determine the potential impact of ranaviruses and *Bd*, we sampled Green Salamanders from known historic locations as well as new locations with ideal habitat in southwestern Virginia (Dickenson, Scott, Washington, and Wise counties; Fig. 1; VDGIF 2014) and tested them for infection by these pathogens. Multiple observers searched rock crevices and surrounding trees and mid-story vegetation for Green Salamanders from May–August 2013. We also used burlap bands at three sites to intercept Green Salamanders climbing trees (Thigpen et al. 2010), but burlap proved to be ineffective due to repetitive damage from mammals, presumed to be Black Bears (*Ursus americanus*). Once located, we captured Green Salamanders by hand, while wearing nitrile gloves (Fisher Scientific, Pittsburg, Pennsylvania USA), and placed salamanders in individual 1.2-liter plastic bags, where they remained throughout processing and until released. We measured both snout–vent length (SVL) and total length (TL) using dial calipers to assess life stage (adult, subadult, juvenile; Waldron and Humphries 2005). To sample for ranavirus (N = 38), we followed procedures of Hamed et al. (2013) and used sterilized stainless steel forceps to collect a small tail section

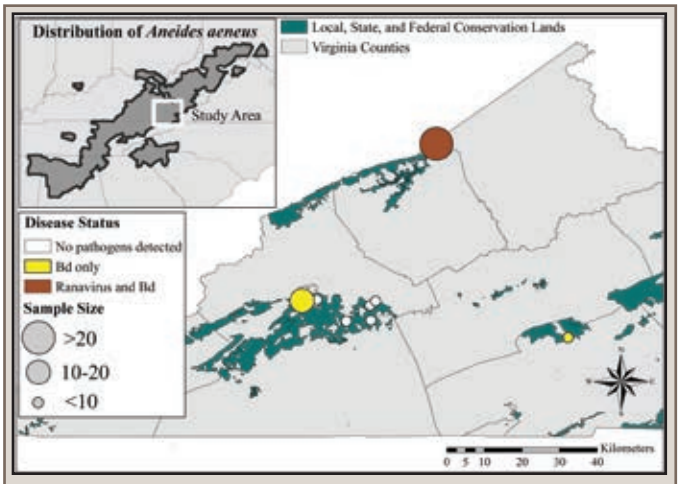

FIG. 1. Distribution of sampling sites and presence of ranavirus and *Batrachochytrium dendrobatidis* (Bd) for *Aneides aeneus* across four counties in southwest Virginia, USA. The diameter of the symbol for each sampling locality is proportional to the sample size at each site. Inset map indicates U.S. states and location of study area (white box) relative to the distribution of *A. aeneus* (dark gray).

from a natural break point. Each sample was placed in a sterile, 2-ml microcentrifuge tube with 99% reagent grade isopropyl alcohol. We did not sample for ranavirus if a salamander had tail damage, and we also excluded female salamanders guarding eggs. To sample for *Bd* infection (N = 41), we swabbed each Green Salamander with a Dryswab™ with wire shaft and rayon bud swab (MW&E, England). First, we swabbed each flank 5 times, then the ventral surface 10 times, and finally the bottom of each foot 5 times (Chatfield et al. 2012). Swab tips were placed in separate microcentrifuge tubes with 99% reagent grade isopropyl alcohol. We released all salamanders at their original location of capture. Bags and gloves were changed and forceps autoclaved after each use.

Genomic DNA was extracted from tail samples and swabs using Qiagen DNeasy Blood and Tissue Kits (Qiagen Inc., Valencia, California, USA) and then quantified utilizing a Qubit™ fluorometer (Life Technologies Corp., Carlsbad, California, USA). We used quantitative real-time PCR (qPCR) utilizing an ABI 7900HT PCR system (Life Technologies Corp.). For ranavirus testing, we used identical primers and protocol of Gray et al. (2012) and ran samples in duplicate. We utilized two positive (cultured virus and DNA from a confirmed positive animal) and two negative (water and DNA from a known negative animal) controls. We deemed samples to be positive if C_T value ≤ 30, based on a 95% confidence interval that we derived from a standard curve originating from runs with known concentrations of virus (Caraguel et al. 2011). For *Bd* testing, we also used qPCR following the procedure and primers of Boyle et al. (2004) and ran samples in duplicate. We repeated analysis if C_T values differed by more than 1 C_T value. We used two positive (DNA from a *Bd* culture and DNA from a confirmed positive animal) and two negative (water and DNA from a known negative animal) controls. We considered samples to be positive for *Bd* infection if C_T value ≤ 35, which was similarly based on a 95% confidence interval derived from a standard curve (Caraguel et al. 2011). All DNA extraction and PCR testing was conducted in the Center for Wildlife Health at the University of Tennessee. We established 95% confidence intervals (CIs) for prevalence using Lowry (2014) 2-sided CIs from a single proportion.

Our survey is the first known to document ranavirus and *Bd* infections in Green Salamanders (Miller et al. 2011; Hughey et al. 2014). We did not observe co-occurrence of pathogens in a single individual, but we did within the same site (Breaks Interstate Park; Fig. 1). We sampled a total of 42 Green Salamanders (21 adults, 15 subadults, and 6 juveniles), but due to tail damage, escape, or females guarding eggs we did not collect a tail sample or swab from every individual. We sampled 38 Green Salamanders for ranavirus, and salamanders averaged 41.22 ± 1.90 (mean ± SE) mm in SVL. Ranavirus prevalence was 8% (3/38), and no salamanders testing positive for ranavirus displayed external signs of infections (Table 1; Miller et al. 2011). Only one Green Salamander testing positive for ranavirus was an adult (50 mm SVL) while the remaining two salamanders were both subadults (40 mm SVL each). Green Salamanders infected with ranavirus were collected only from the Breaks Interstate Park (Dickenson Co.; Fig. 1), which had the greatest number of Green Salamanders encountered during the survey.

We swabbed 41 Green Salamanders for *Bd*, and salamanders averaged 42.70 ± 1.89 mm SVL. We detected *Bd* in 6 of 41 (15%) sampled Green Salamanders (Table 1). Two Green Salamanders infected with *Bd* were adults (52 and 57 mm SVL), whereas the other four were subadults (32–42 mm SVL). Only one salamander that tested positive for *Bd* displayed external signs of illness (e.g., emaciation). However, another Green Salamander was thin but not emaciated and did not test positive for either pathogen. Plethodontid salamanders from Mexico that were *Bd*-positive also lacked clinical external signs, thus suggesting positive salamanders do not always exhibit external signs of disease (Rooij et al. 2011). Green Salamanders infected with *Bd* were collected from Breaks Interstate Park (N = 4), Flag Rock (N = 1; Wise Co.), and Brumley Cove Camp (N = 1; Washington Co; Table 1; Fig. 1).

Due to the cryptic behavior of Green Salamanders and the presence of nesting females, we were only able to sample a single individual at six locations and are therefore cautious about inferring the potential disease status of these populations. However, two locations (Breaks Interstate Park, N = 22; Flag Rock, N = 13) provided a sufficient sample size to evaluate disease status. Only the Breaks Interstate Park had ranavirus-positive individuals, and this location was much lower in elevation (553 m) than Flag Rock (983 m), where no Green Salamanders tested positive for ranavirus. A similar trend was observed in the Great Smoky Mountains National Park where ranavirus prevalence was greater in salamander communities at lower elevation sites (Gray et al. 2009b; Sutton et al. 2014). However, our two sites were separated by almost 50 km and could have been influenced by other factors, including variation in temperature and moisture that have also been linked with ranavirus prevalence (Sutton et al. 2014). The Breaks Interstate Park also had the highest prevalence for *Bd*. A seep and subsequent stream were adjacent to three rock crevices at the Breaks Interstate Park. Both ranavirus and *Bd* are associated with streams and aquatic environments (Lips et al. 2006; Sutton et al. 2014).

Green Salamanders are not typically associated with aquatic habitats, but other hosts (i.e., those associated with aquatic habitats) may be transmitting one or both of these pathogens. For example, ranavirus has been demonstrated to be transmitted by an infected individual to an uninfected individual following a short contact time (Brunner et al. 2007). Also, *Bd* can be passed via water containing zoospores (Carey et al. 2006) and can survive for up to three months in river sands, thus suggesting moist rock ledges could harbor *Bd* (Johnson and Speare 2005). Brumley

TABLE 1. Ranavirus and *Batrachochytrium dendrobatidis* (*Bd*) prevalence in Green Salamanders (*Aneides aeneus*) from Southwest Virginia, USA, May–August 2013. I = total number of infected individuals; N = total number sampled.

Location	*Bd* I / N	Prevalence (95% CI)	Ranavirus I / N	Prevalence (95% CI)
Breaks Interstate Park (37.2947°N; 82.4505°W)	4 / 22	0.18 (0.07–0.39)	3 / 22	0.14 (0.05–0.33)
Flag Rock (36.9194°N; 82.6268°W)	1 / 13	0.08 (0.01–0.33)	0 / 14	0 (0–0.22)
Brumley Cove Camp (36.8315°N; 81.9901°W)	1 / 1	1.00 (0.21–1.00)	—	—
Clear Creek Gorge (36.9217°N; 82.5908°W)	0 / 1	0 (0–0.79)	0 / 1	0 (0–0.79)
Guest River Gorge (36.9183°N; 82.4505°W)	0 / 1	0 (0–0.79)	—	—
Jaybird Branch (36.9081°N; 82.4638°W)	0 / 1	0 (0–0.79)	0 / 1	0 (0–0.79)
Kitchen Rock (36.8703°N; 82.5208°W)	0 / 1	0 (0–0.79)	—	—
Little Stony Gorge (36.8726°N; 82.4623°W)	0 / 1	0 (0–0.79)	—	—
Total	6 / 41	0.15 (0.07–0.28)	3 / 38	0.08 (0.03–0.27)

Cove Camp had a *Bd*-positive individual and a large stream (Brumley Creek) that drains a reservoir (Hidden Valley Lake) is within a few meters of the rock face. We observed *Desmognathus ochrophaeus* (Alleghany Mountain Dusky Salamander) on the Brumley Cove Camp rock faces. In southwest Virginia, two sister species, *D. ochrophaeus* and *D. orestes* (Blue Ridge Dusky Salamander), have tested positive for ranavirus (Davidson and Chambers 2011a; Hamed et al. 2013) and the former also has tested positive for *Bd* (Davidson and Chambers 2011b). Thus, it is possible that salamanders of the genus *Desmognathus* could be moving both ranavirus and *Bd* out of aquatic systems to rock crevices. Flag Rock had no flowing or standing water, and only a single salamander tested positive for *Bd*, with no ranavirus infections.

The only observation of negative pathogen impacts was the emaciated Green Salamander that tested positive for *Bd* infection. We did not collect tissue samples for histological examination, but the animal was also lethargic. Anurans with *Bd* infections are often emaciated, with symptoms persisting for 2–3 months after clearing *Bd* infections (Parker et al. 2002). However, emaciation does not always imply a *Bd* infection, as anurans with parasite infections often appear emaciated (Young et al. 2012). We are cautious in assigning the condition of this salamander to *Bd* without histological evidence, but our results warrant further sampling, including histological examination and surveys for visibly infected or dead Green Salamanders.

Our finding of both ranavirus and *Bd* in Green Salamanders for the first time suggests that both pathogens could impact Green Salamander populations. Due to the conservation status of Green Salamanders throughout their range, our findings support implementation of range-wide monitoring. These results also confirm that Green Salamanders can be infected by either or both pathogens, suggesting that past declines could have been influenced by pathogens. Ranavirus prevalence has been shown to increase in drought years (Gray et al. 2009b; Sutton et al. 2014), and thus future long-term monitoring is warranted at yearly intervals to detect possible infection trends, especially on dry rock outcrops. Lastly, on rock faces where other amphibians are utilizing the same rock ledges or those in close proximity to known Green Salamander crevices, a broader sampling effort would determine if other amphibians are potentially spreading ranavirus and/or *Bd* from aquatic environments to rock faces inhabited by Green Salamanders.

Acknowledgments.—This research was completed with funds provided by the Virginia Department of Game and Inland Fisheries through a State Wildlife Grant from the U.S. Fish and Wildlife Service, the University of Tennessee Institute of Agriculture, the Virginia Community College System Paul Lee Professional Development grant, and the UVa-Wise Fellowship in the Natural Sciences endowment. We thank Becky Hardman for assistance with molecular testing and extraction. Additionally, we are grateful to the USFS staff for project assistance and to many private land owners for access to our study sites. All sampling was approved by the Virginia Department of Game and Inland Fisheries (Scientific Collection Permits #41396 and #43904).

A Report of Ranavirus Infecting Midland Painted Turtles with Novel Localities for Frog Infection in Northwest Ohio

Amphibian die-offs attributed to ranaviruses (genus *Ranavirus*, Family Iridoviridae) continue to be reported from around the world (Gray et al. 2009; Duffus et al. 2015), and constitute one of the single most important factors in mass mortalities in the United States in recent years (Green et al. 2002). Continued reporting is important as it affords an opportunity to monitor the spread and distribution of the pathogen (Muths et al. 2006), identify affected species (Duffus et al. 2015), potentially compare viral genomes (e.g., Tan et al. 2004), and study the long-term effects of viral infections on host survival in local populations (Gray et al. 2009).

In September 2011, during the third year of a routine, biweekly sampling of frogs at a five-year old, 1-ha, mitigated wetland named Spurgat's Wetland in Hancock County in northwest Ohio, USA (40.9905°N, 83.7596°W), dozens of tadpoles and recently metamorphosed American Bullfrogs (*Lithobates catesbeianus*) were found dead or moribund at the water's edge. Most exhibited edema, diffuse petechial lesions, and bloating, which are signs of ranavirus documented in Wood Frogs (*Lithobates sylvaticus*) by Brunner et al. (2011). Over the next four weeks (September through November 2011), we surveyed for dead or moribund frogs on six different occasions, during which we collected three dead Bluegill fishes (*Lepomis macrochirus*), two Midland Painted Turtles (*Chrysemys picta marginata*), and 139 dead or moribund tadpoles, recently transformed larvae, or adult frogs, all ≤ 55 mm snout–vent length that were either *Lithobates catesbeianus* or *L. clamitans* (Table 1).

Whole dead or moribund frogs were collected and transported in sterile, plastic bags to the laboratory for both gross examination and genetic testing for the presence of ranavirus (Table 1). Liver samples (~ 5 mm in diameter) were taken from 13 whole frog specimens and immediately frozen at -20°C for use in molecular analysis before the whole specimen was fixed in formalin. All tools used for liver sample collection were rinsed between each specimen in 50% bleach solution for 20 minutes and thoroughly rinsed in sterile distilled water. The life stage of whole frog specimens was determined as described by (Gosner 1960) and physical signs of disease were noted. Skin swab samples were collected using sterile, single use, cotton-tipped transport swabs with a plastic shaft. Skin swab samples were transported on wet ice to the laboratory where DNA extraction was performed.

DNA was extracted from both liver and skin swab samples for molecular analysis using DNeasy Blood and Tissue Kit (Qiagen, Valencia, California) following the manufacturer's protocol. Extracted DNA was used to perform conventional PCR of two targets in the major capsid protein (MCP) gene using previously published gene specific primers, including: MCP1, MCP6R, M153, and M154 (Hyatt el al. 2000, Marsh et al. 2002). Each PCR reaction was carried out using established methodology (Hyatt el al. 2000, Marsh et al. 2002). Samples showing an approximate amplicon size of 1300 bp (MCP1 / 6R primer set) or 600 bp (M153 / 154 primer set) after gel electrophoresis were sent to the University of Chicago Comprehensive Cancer Center DNA Sequencing and Genotyping Facility for Sanger sequencing.

			Overall Total	144	77

All forward and reverse sequences were assembled into contigs using the assembly function in Geneious™ version 6.0 (Biomatters, New Zealand; www.geneious.com), and any ambiguous nucleotides were corrected using the electropherogram as reference. The average nucleotide length (bp) of PCR products for reactions using MCP1 / 6R primer set was 1365 bp (± 15 bp, standard deviation). For the M153 / 154 primer set, average nucleotide length was 593 bp (± 29 bp, standard deviation). Reference ranavirus sequences were downloaded from GenBank (Accession Numbers: GU391284, DQ897669, FJ459783, FVU36913, AB474588, FJ515796, AY03363, HM133594, GU391285, DQ335253). Sequences were aligned in BioEdit version 7.2.5 (http://www.mbio.ncsu.edu/bioedit/bioedit.html) and a nucleotide query was performed using Blast (http://blast.ncbi.nlm.nih.gov/Blast.cgi). There was 100% identity between sequences collected in this study and the type ranavirus frog virus sequence (FV3; GenBank Accession Number AY548484). The experimental sequences from this study covered nucleotide regions 41–1393 of the type FV3 protein coding reference sequences, representing 97% of the full MCP coding sequence. Based on the number of successful PCR amplicons in all of the samples, ranavirus was confirmed in approximately 53.5% of the samples (Table 1).

Ranavirus was previously identified in central Ohio (Homan et al. 2013) in *Ambystoma maculatum, L. catesbeianus, L. clamitans, L. sylvaticus,* and *Anaxyrus americanus*, and our study expands the known distribution of ranavirus into new localities in northwestern Ohio. Ranavirus in frogs has also been detected in surrounding states including Illinois, New York (Brunner et al. 2011), Pennsylvania (Glenney et al. 2010), and Tennessee (Green et al. 2002; Gray et al. 2009). Genetic sequences produced in this study confirm that ranavirus may also be found in Midland Painted Turtles (*Chrysemys picta marginata*) in Ohio. Ranavirus has been isolated from other naturally-occurring populations of North American turtle species, including: the Eastern Painted Turtle (*C. picta picta;* Goodman et al. 2013), Eastern Box Turtle (*Terrapene carolina carolina*; DeVoe et al. 2004, Johnson 2008, Ruder et al. 2010, Allender et al. 2011, Allender et al. 2013), Florida Box Turtle (*Terrapene carolina bauri*; Johnson 2008), and the Common Musk Turtle (*Sternotherus odoratus;* Goodman et al. 2013). Ranavirus was not detected in any of the three Bluegill fish (*L. macrochirus*), even though FV3-like ranaviruses are known to infect fishes (e.g., Mao et al. 1999; Brenes et al. 2014), but the advanced state of decomposition of the fishes may have prevented successful detection of ranavirus using the molecular techniques in this study.

Continued biological sampling and ecological monitoring of amphibians in Spurgat's Wetland in northwestern Ohio will allow appropriate documentation of the ecology of ranavirus. Dedicated sampling and monitoring is necessary to determine the long-term impact that ranavirus may have on the organismal community in Spurgat's Wetland. The current study adds to the growing body of literature concerning the impact of ranavirus on various populations, and continued monitoring and sampling will further contribute to our understanding of its distribution, virulence, and impact on herpetological and non-herpetological (e.g., fishes) populations.

Relationship between the Water Temperature Experienced by Captive Loggerhead Turtles (*Caretta caretta*) and Eggshell Formation

Loggerhead Turtles, *Caretta caretta*, have a worldwide distribution, encompassing temperate and tropical oceans (Pritchard 1997). Adult female Loggerhead Turtles tend to migrate long distances from foraging areas to breeding areas (Miller 1997). Subsequently, they mate with males and then lay several clutches of eggs on sandy beaches, which are separated by approximately two-week internesting intervals (the period between nesting and next nesting) during a single nesting season (Miller 1997). Although vitellogenesis (i.e., ovarian growth) of sea turtles may continue into the early nesting season (Wibbels et al. 1990), it is almost complete prior to nesting season (i.e., migrating and mating season) (Rostal et al. 1996; 1998; 2001; Hamman et al. 2003; Rostal 2005, 2007). First ovulation may be induced by the mating stimulus (Manire et al. 2008), and all subsequent ovulations occur immediately after each nesting event (Licht et al. 1979, 1980, 1982; Licht 1982; Wibbels et al. 1992). Mature follicles which are ovulated are subsequently fertilized, covered with albumen, and are finally surrounded by an eggshell in preparation for the laying (Owens 1980; Rostal 2005, 2007).

The internesting intervals for Loggerhead Turtles vary between 9 and 28 days (Dodd 1988), with this variation being influenced by water temperature. Mrosovsky (1980) reported a negative correlation between internesting intervals and the ambient water temperature experienced by wild Loggerhead Turtles, followed by similar findings by Sato et al. (1998) and Hays et al. (2002). Although the thermal mechanism of this phenomenon is still unclear, Sato et al. (1998) hypothesized that the pre-ovipositional development of eggs during the internesting periods seems to be expedited by high water temperature, because the body temperature of Loggerhead Turtles is dependent on the ambient water temperature (Sato et al. 1994, 1995, 1998). Their results led to the assumption that egg formation is regulated by both water and body temperature. Yet, this hypothesis has not been confirmed to date. To test this hypothesis, the relationship between ambient water temperature and egg formation process in captive Loggerhead was explored. A study performed in captivity using ultrasonography, within which it is possible to follow the reproductive events (e.g., nesting and internesting) of identifiable individual turtles and nests, would provide information about egg development during the internesting intervals over the course of a season (Rostal et al. 1990, 1996, 1997; Rostal 2005, 2007; Kawazu et al. 2014b); such a study would not be possible to undertake in the wild.

In the current study, the egg development of two captive Loggerhead Turtles was recorded during the internesting periods, along with the daily water temperatures of the tanks over a 6-yr period. Ultrasonography was used to observe the oviducts of both turtles at regular intervals to determine the relationship between the water temperature experienced by the turtles and egg formation.

In 1994, two adult female Loggerhead Turtles (referred to as Turtle 1 and 2) were incidentally captured in the set-nets of fishing boats operating around Okinawa Island, and were subsequently

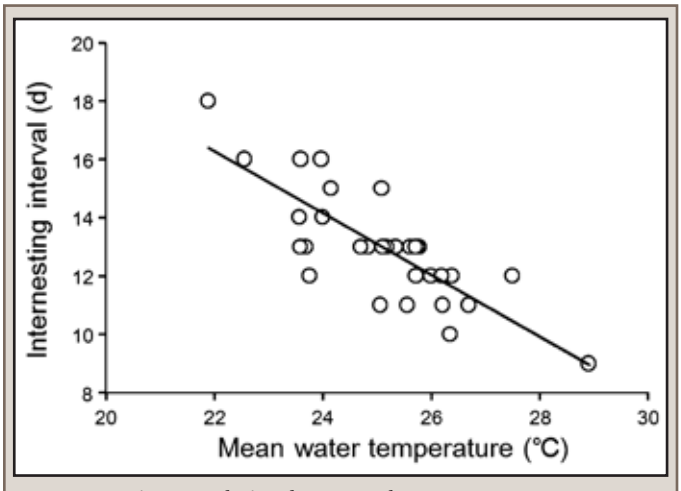

FIG. 1. Negative correlation between the mean water temperature and internesting intervals for two captive Loggerhead Turtles *Caretta caretta*. Mean water temperatures were averaged for each internesting interval. The regression line is shown by Y = -1.06X + 39.58 (Spearman's rank correlation coefficient = -0.8, N = 32, P < 0.001).

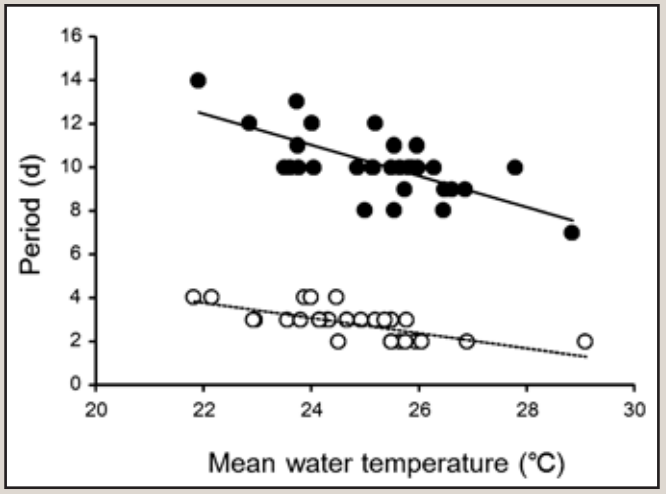

FIG. 3. Relationship between the mean water temperature and the days from egg laying to the onset of eggshell formation (early egg formation period) and from the onset of eggshells formation to the subsequent egg-laying event (late egg formation period) for two captive Loggerhead Turtles *Caretta caretta*. Open and solid circles indicate the periods for early and late egg formation, respectively. The mean water temperatures were averaged for each period. The regression line of the early and late egg formation period is shown by Y = -0.33X + 11.03 (Spearman's rank correlation coefficient = -0.71, N = 32, P < 0.01) and Y = -0.73X + 28.6 (Spearman's rank correlation coefficient = -0.71, N = 32, P < 0.001), respectively.

kept in captivity at the Ocean Expo Park, Motobu-tyo, Okinawa Prefecture, Japan. The two turtles were kept for the development of a captive breeding program (Teruya et al. 1997), and were maintained under conditions based on the ethical guidelines for animal exhibition and research of JAZA (Japanese Association of Zoos and Aquariums). The holding tank (16.8 × 10.5 × 2 m, outdoors) had an open-water system and a sandy nesting area (115 m^2) (Teruya et al. 1997). The water temperature of the tank was measured daily, ranging between 20°C and 30°C across a 12-month period. This water temperature range was similar to that experienced by Loggerheads under natural conditions (sea surface temperature), at least around Okinawa Island. The turtles were fed at 24-h intervals, with a diet that included fish and squid in quantities equivalent to 2% of their body weight. A male Loggerhead Turtle was also present in the holding tank since 1994, with which the two turtles mated at 1- to 2-year intervals, and subsequently nested on the sandy area (Teruya et al. 1997). The straight carapace length and body weight of the two females turtles between 2007 and 2013 were 940 ± 0.5 mm (mean ± SD) and 126.6 ± 4.9 kg for Turtle no. 1 and 829 ± 0.2 mm and 103.8 ± 4.8 kg for Turtle no. 2, respectively. The number of clutches (nesting) per season of both turtles combined was 4.2 ± 1.0 (Turtle no. 1: 4.2 ± 1.3 days, Turtle no. 2: 4.2 ± 0.8 days; Table 1). For both turtles, lengths of all internesting intervals and clutch sizes were recorded according to the method described by Miller (1999). Specifically, clutch size was measured as the number of eggs with albumen and yolk (normal eggs).

Beginning one day after each nesting event to the onset of eggshell formation, we observed the left and right ovaries and oviducts of both turtles daily by using ultrasonography with a 5-MHz probe (Mini-dock P04341-04, Sonosite Inc., USA). The turtles were placed in dorsal recumbency, and the probes were positioned in the inguinal region of both the right and left rear flippers at a water depth of 200 mm, as described previously (Kawazu et al. 2014b). We used the results of this procedure to document the number days from egg laying to the onset of eggshell formation (early egg formation period). In addition, we also documented the number days from the onset of eggshell formation to the subsequent egg-laying event (late egg formation period) by subtracting the early egg formation period from the internesting interval. Spearman's rank correlation coefficient was calculated for mean water temperature versus the internesting intervals, the early egg formation period, and the late egg formation period for both turtles combined.

The mean clutch size of both turtles combined was 113 ± 17.6 eggs (Turtle no. 1: 121.8 ± 14.2 eggs, Turtle no. 2: 104.1 ± 16.5 eggs). The mean internesting intervals of both turtles combined were 13 ± 1.9 days (Turtle no. 1: 13.3 ± 1.9 days, Turtle no. 2: 12.6 ± 1.8 days). During these nesting periods, the water temperature in the holding tank was between 20.5°C and 29.2°C. There was a significant negative correlation between mean water temperature and internesting interval for both turtles (Fig. 1; Spearman's rank correlation coefficient = -0.80, N = 32, P < 0.001).

Ultrasonography clearly showed the presence of vitellogenic follicles (Fig. 2A) and calcified eggs (Fig. 2B). Therefore, we were able to confirm the day that eggshell formation started. However, we could not distinguish oviductal eggs without shells after ovulation from ovarian follicles. The mean early egg formation period was 2.8 ± 0.7 days in both turtles combined (range: 2–4 days). There was a significant negative correlation between mean water temperature and the early egg formation period for both turtles (Fig. 3; Spearman's rank correlation coefficient = -0.71, N = 32, $P < 0.01$). In contrast, the mean late egg formation period was 10.6 ± 1.5 days (range: 7–14 days). There was a significant negative correlation between mean water temperature and the late egg formation period for both turtles (Fig. 3; Spearman's rank correlation coefficient = -0.71, N = 32, $P < 0.001$).

This study confirmed the negative correlation between mean water temperature and internesting interval for two captive Loggerhead Turtles, supporting the thermal trends documented for wild loggerheads by Mrosovsky (1980), Sato et al. (1998), and Hays et al. (2002) (Fig. 1). Miller (1997) reported a mean of 3.49 clutches per season for loggerheads, with an internesting interval of 14 days and clutch size of 112.4 eggs. These parameters appeared to be similar to those recorded in the current study (mean of 4.2 clutches, internesting intervals of 13 days, and 113 eggs per clutch). Although the remigration intervals of wild nesting loggerheads are averaged approximately 2- to 3-year (Miller 1997; Schroeder et al. 2003), the fewer intervals, such as captive loggerheads (1- to 2-year), are also observed in wild (Dodd 1988; Schroeder et al. 2003; Kawazu et al. 2014a). Therefore, we assumed that reproductive parameters in the captive animals reflected those of wild animals. In addition, we observed a negative correlation between each mean water temperature and early and late egg formation periods during the interesting intervals (Fig. 3). This result indicates that the egg formation process is influenced by temperature, supporting the hypothesis of the relationship between water temperature and the egg formation. We suggest that the egg formation process is expedited by the ambient water temperature experienced by turtles, which results in the documented shorter internesting intervals at higher temperatures and with nesting progression.

In sea turtles, ovulation, fertilization, and covering of the fertile yolk with albumen are completed before eggshell formation (Owens 1980). Unfortunately, ultrasonography could not determine the period of ovulation after nesting in the captive loggerheads. However, some previous studies have demonstrated the periovulatory period of some sea turtles species on the basis of changes in the levels of follicle follicle-stimulating hormone (FSH), luteinizing hormone, and progesterone. For instance, wild green and Loggerhead Turtles ovulate from 20 to 50 h after nesting (Wibbels et al. 1992). Other physiological studies have shown that Green Turtles ovulate 6 to 48 h after nesting, while Olive Ridley Turtles, *Lepidochelys olivacea*, ovulate from 1 to 3 days after nesting (Licht et al. 1979, 1982). In addition, Kawazu et al. (2014b) reported that egg formation occurred one day after ovulation based on the administration of FSH to Hawksbill Turtles, *Eretmochelys imbricata*. These previous studies indicate that eggshell formation tends to start within four days of nesting. In the current study, these similar results demonstrated that the early egg formation period (before eggshell formation) occurred within 2–4 days of egg laying in the two captive loggerheads. Fertilization and covering of fertile yolk with albumen also occur during this period, because the egg formation process follows this ordering after ovulation, ending with eggshell formation

(Owens 1980). Even though we could not use ultrasonography to document the day on which egg formation was completed, Miller (1985) described the eggshell as not being fully formed until at least 7 days after ovulation. This previous study indicates that yolk fertilization and/or albumen secretion in the oviducts simultaneously progress with eggshell formation. A review by Hamann et al. (2003) stated that eggshell formation is complete at 9–10 days after ovulation, which is similar to the mean late egg formation period (eggshell formation period) documented in the current study (mean: 10.6 ± 1.5 days). Thus, egg formation may be completed just before the subsequent nesting event, at least a few days beforehand.

Mature follicles are likely to be covered with albumen in the anterior glandular region of the oviduct, after which they are surrounded by eggshells in the shell-forming region, which has the function of protein carbohydrate shell membrane formation and calcium deposition (Solomon and Baird 1976, 1979; Owens 1980; Rostal et al. 1997; Rostal 2005, 2007). During the internesting intervals, sea turtles must rapidly provide albumen (i.e., protein) and eggshell (i.e., calcium) for egg development (Wallace et al. 2006). The plasma total protein and calcium levels of Loggerheads during nesting are significantly higher than those during foraging (Deem et al. 2009). These blood parameters significantly drop with the progression of each nesting event in Hawksbill Turtles (Goldberg et al. 2013) and the calcium level remain in Kemp's Ridley Turtles (Rostal et al. 1998) and Leatherback Turtles *Dermochelys coriacea* (Rostal et al. 2001) during nesting. These reduction and maintenance of two blood parameters with nesting progression may indicate the utilization for egg formation (i.e. albumen and eggshell) throughout the metabolic process of protein and calcium. Loggerheads use metabolic heat production to maintain their body temperatures slightly higher than the ambient water temperature; thus, water temperature influences the internesting interval (Sato et al. 1994, 1995, 1998). Hence, faster egg formation at higher water temperature indicates that the elevated temperature may accelerate the metabolism of compounds for egg formation in turtles. Consequently, the internesting interval may be shorter at higher temperatures and with the progression of nesting, as inferred by previous field studies (Sato et al. 1998). Further studies on the thermal mechanism of captive sea turtles during nesting need to be performed by controlling the water temperature.

Acknowledgments.—We express our deep gratitude to H. Miyahara (Director) of Okinawa Churaumi Aquarium for providing us with valuable suggestions and comments on this study. We are grateful to the staff responsible for the captive sea turtles at the Okinawa Churashima Foundation for their assistance with loggerhead ovary observations by ultrasonography. We also thank Dr. M. Nakamura of Okinawa Churashima Foundation for advice about the preparation of this manuscript. The Okinawa Prefecture provided permits for the capture and holding of turtles, based on the Fishery Act in Japan.

Feeding Frequency Influences Weight Gain Independently of Dietary Intake in Juvenile *Boa constrictor* (Squamata, Boidae)

The somatic growth rate of snakes may be defined by feeding frequency and the amount of food intake (Barnard et al. 1979; Taylor and Denardo 2005; Penning and Cairns 2012). In studies where snakes were separated into different feeding groups, treatment groups that ate more frequently (Myer and Kowell 1973; Taylor and Denardo 2005) or consumed larger amounts of food in the same time interval (Forsman and Lindell 1996; Penning and Cairns 2012) grew more rapidly and were larger than snakes in groups fed with a lower frequency or at a lower prey mass to snake body mass ratio. However, studies on growth rates in snakes have generally focused on feeding frequency (Taylor and Denardo 2005) or the amount of food ingested (Barnard et al. 1979; Forsman and Lindell 1996; Penning and Cairns 2012), with few relating these two variables (Myer and Kowell 1973). Furthermore, in these studies, the amount of food and frequency of the feedings were not controlled in relation to each other or to body size (but see Penning and Cairns 2012). Thus, it is difficult to accurately infer the effects of feeding frequency and food intake based on these results because animals eating weekly ingest a greater amount of food (twice as much) than individuals eating biweekly if individual meal size remains constant.

The aim of this study was to evaluate the combined influence of feeding frequency and food mass on the growth rates of snakes in captivity, using juvenile *Boa constrictor* as a model. As far as we can tell, this is the first study that seeks to evaluate growth in snakes using these standardizations. *Boa constrictor* has a wide distribution, occurring from northern Mexico to central Argentina (Pope 1961; Vanzolini et al. 1980), feeds on mammals, birds, and lizards (Vanzolini et al. 1980; Pizzatto et al. 2009; Gondim et al. 2012; Rodrigues et al. 2014), and belongs to the family Boidae, a taxonomic group that has low metabolic rates when compared to other squamates (Chappell and Ellis 1987). To our knowledge, all studies evaluating growth rates in snakes have focused on species belonging to the families Colubridae or Viperidae (e.g., Dmi'el 1967; Barnard et al. 1979; Taylor and

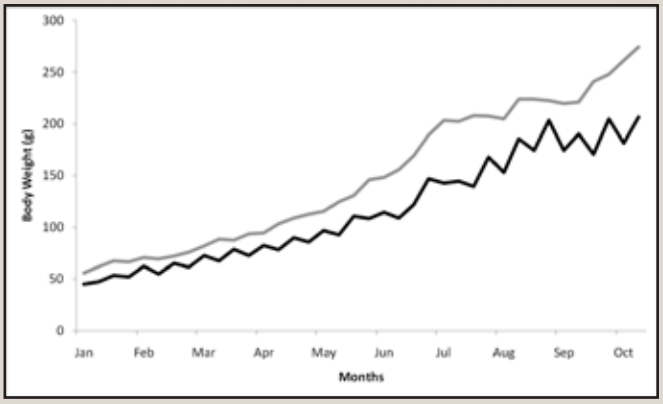

FIG. 1. Growth rate curves of mean body mass (g) for juvenile *Boa constrictor*. Snakes in the weekly group (grey; N = 4) were fed once a week with mice weighing 10% of their body mass; those in the biweekly group (black; N = 5) were fed every other week with mice weighing 20% of their body mass.

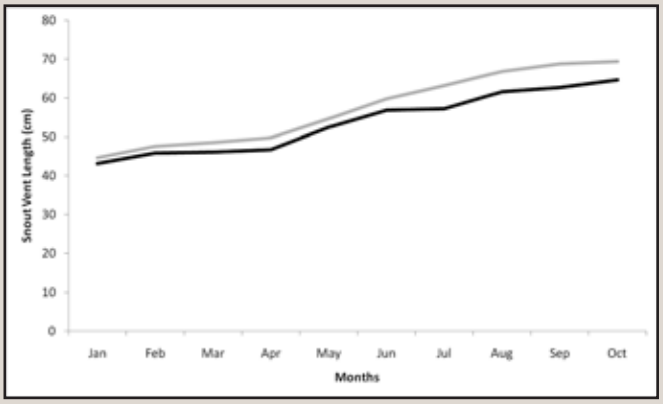

FIG. 2. Growth rate curves of mean snout–vent length (cm) for juvenile *Boa constrictor*. Snakes in the weekly group (grey; N = 4) were fed once a week with mice weighing 10% of their body mass; those in the biweekly group (black; N = 5) were fed every other week with mice weighing 20% of their body mass.

Denardo 2005; Penning and Cairns 2012); therefore, *B. constrictor* represents a suitable model for studying the influence of prey size and feeding frequency on the growth rate of snakes. Additionally, this work seeks to aid in improving the husbandry and breeding of *B. constrictor* in captivity, since this species is commercially bred for the pet trade and is commonly raised as pets throughout the world.

Materials and methods.—The juvenile *Boa constrictor* used in this study originated from a litter born at the Núcleo Regional de Ofiologia da Universidade Federal do Ceará (NUROF-UFC) on 28 November 2012. The litter was randomly divided into two groups, which were not statistically different in body mass or body length (body mass: Mann-Whitney U = 17, $P = 0.11$; body length: Mann-Whitney U = 4, $P = 0.17$; see Table 1): Group 1 (weekly) with four individuals and Group 2 (biweekly) with five individuals. The study period extended from January to October 2013, totaling 10 months.

The animals were housed individually in cylindrical plastic tubs (26.5 cm in diameter and 36.5 cm in height) with small perforations to allow the passage of air. Sheets of newspaper were used as substrate. After nine months of the experiment, the snakes were relocated to wooden boxes (31 × 47 × 31 cm [L × W × H]) with small perforations in the sidewalls for the passage of air. Newspaper continued to serve as substrate. Enclosures were cleaned weekly for both groups, and water was offered *ad libitum*. Snakes did not have access to artificial heat sources because the ambient temperature of the room where the animals were kept remained around 30°C.

Initially, from December 2012 to early January 2013, all snakes were fed biweekly with mice equivalent to 10% of their body mass. From January 2013 onward, snakes from Group 1 were fed weekly on mice with a mass equivalent to 10% of their body mass, while snakes from Group 2 were fed biweekly (every other week) on mice with a mass equivalent to 20% of their body weight. Although subject to different feeding frequencies, all animals consumed the same amount of food within a two-week interval, which was 20% of their body mass.

All snakes (including the biweekly group) were weighed on a digital scale every week prior to feedings. The snout to vent length (SVL) of each individual was measured monthly using a thin cord that was aligned along the spine of the animal; this cord was then measured with a ruler.

The net gains in body mass and SVL at the end of the experiment (the difference between the final measurements and those taken at the beginning of the study) were evaluated using Mann-Whitney U tests. This test was also used to verify the differences between the initial weights and SVLs among the groups. In order to ensure that our results were not limited or biased by the small sample size in each group, a null model was performed in which 1000 numbers were obtained from a normal distribution, with mean and standard deviation equal to the values obtained when all of the snakes were considered as a single group. Next, we randomly sampled four and five numbers and evaluated if there was a difference between these groups using the Mann-Whitney test. Since both groups were collected from the same population (the 1000 numbers generated), no difference was expected between them. Finally, we report how many times we found this lack of difference, divided by the number of samplings performed (this ratio is hereafter referred to as "efficiency"), representing how well our sampling design is able to represent the real population. This null model was performed in our study using 1000 comparisons between groups randomly generated from sampling. Statistical analyses were performed in R ver. 2.15.3 (R Development Core Team 2012), and descriptive statistics are reported as mean ± standard deviation.

Results.—Mean body masses and SVLs of snakes in the two groups are shown in Table 1. After ten months, the general pattern of weight gain differed for weekly and biweekly groups (Fig. 1). For the group of snakes fed weekly, weight gain was constant and ever-increasing from the start of the experiment until July 2013, when there was a change in the pattern of weight gain in this group, becoming irregular and even showing decreases between samples. Body mass was also increasing for the biweekly group, but this group showed large increases in mass the week after a feeding. Decreases in mass were observed the following week (just before feeding again), but these reductions were slightly smaller than the gains in the postprandial week.

At the end of the experiment, snakes in the weekly group had an average net gain of 207.51 ± 27.54 g, whereas the biweekly group had an average net gain of 136.75 ± 47.81 g. There were significant differences in net weight gain (U = 19, $P = 0.03$, efficiency = 0.968) and final mass (U = 19, $P = 0.03$, efficiency = 0.965) between the groups at the end of the experiment. These high values of efficiency suggest that these significant differences

Table 1. Average snout–vent lengths and body masses of *Boa constrictor* in this study. Statistics are presented as mean ± standard deviation.

Group	N	Snout–vent length (cm)		Mass (g)	
		Initial	Final	Initial	Final
Group 1 (weekly)	4	36.62 ± 1.70	69.40 ± 4.77	53.98 ± 2.77	261.49 ± 29.17
Group 2 (biweekly)	5	38.70 ± 1.64	64.60 ± 7.09	44.87 ± 7.29	181.62 ± 53.34
Groups 1 & 2 (combined)	9	37.77 ± 1.90	66.73 ± 6.33	48.92 ± 7.24	217.12 ± 59.28

are real, because if the groups belonged to the same population there is a probability of 96% that this pattern would be recovered. These values of efficiency were very similar to simulated values havin a high number of replicates, such as 100 in each group, been used in our study (efficiencies = 0.967 and 0.973 for net gain and final mass, respectively). There were no significant differences in net gain in SVL at the end of the experiment (U = 16, $P = 0.19$) or in the final SVL (U = 16, $P = 0.17$) between groups (Fig. 2). Together, snakes from both groups had an average net gain of 28.95 ± 6.44 cm in SVL (Table 1).

Discussion.—Net gain in body mass differed between the feeding groups over the course of this study, where snakes fed weekly gained more weight than those fed biweekly. Similar results were found by Myer and Kowell (1973) and Taylor and Denardo (2005) for groups eating more frequently. However, in these studies, the amount of food offered in feeding events was similar for both groups or was not properly quantified. Unlike these works, both dietary groups in the present study ate the same amount of food relative to body mass within a standard two-week interval, and the feeding frequency was still a determining factor in the differential weight gain. Our results also reinforce the assertion that body mass is not a good estimate of age in snakes (also observed in Penning and Cairns 2012), considering that despite having the same age, snakes differed in body mass according to their feeding frequency.

There was no difference in SVL between feeding groups in our study, demonstrating the stability of growth in length, which is more invariant with respect to changes in food consumption patterns (see Fig. 2). However, in other studies, differences in total length (Myer and Kowell 1973) and SVL growth rates (Taylor and Denardo 2005) were observed between groups fed with different frequencies, but the amount of food ingested per feeding event was similar in both experimental groups or sometimes not quantified.

Seven months into the experiment, an adverse effect was observed in the weekly feeding group, with at least one snake regurgitating its prey after each feeding trial. Additionally, snakes in the weekly group sometimes refused food during feeding trials and there was an increase in the amount of feces produced by these animals in the final months of the study (visual evaluation only; feces were not weighed). These results may indicate an overfeeding of this group in terms of feeding frequency and, consequently, a need for changes in feeding schedule and prey size. Although the metabolism of neonatal snakes is high, demanding a high energy input, older snakes do not require a constant food supply due to the accumulation of body reserves (Dmi'el 1967). It may be inferred that in the first seven months of the experiment, individuals in the weekly group accumulated sufficient amounts of corporal reserves where weekly feedings were no longer necessary. In the studies of Dmi'el (1967) and Myer and Kowell (1973), food was offered *ad libitum*, and these authors also observed changes in patterns of prey ingestion. Dmi'el (1967) reported that the snakes increased food intake throughout life, but there was a decrease in the mass ratio of prey items to the body mass of the snakes. Myer and Kowell (1973) noted that snakes changed from eating small amounts of food every day to eating larger prey items less frequently. These results may explain the regurgitations and decreased interest in feeding observed in snakes fed weekly in the present study. Furthermore, weekly feedings may represent the best feeding schedule for juvenile *B. constrictor* during the initial seven to nine months, followed by a change to biweekly feedings with larger prey. Some *B. constrictor* fed biweekly also experienced occasional regurgitations, but not at the frequency seen in the weekly group.

In summary, weight gain in snakes appears to be influenced by feeding frequency. An initial dietary pattern with high feeding frequency and small prey items resulted in rapid growth of juvenile snakes in captivity. Future studies should evaluate the effectiveness of changing this feeding routine after some months to a lower frequency, with larger prey items relative to body mass. Moreover, future studies could also determine the ideal body weights (standardized by body length) of *B. constrictor*, which can then be used as a guideline to determine the best feeding routine for the species in captivity.

Acknowledgments.—We would like to thank all of the friends that assisted us in the feeding trials, Robert Mendyk for his support and suggestions throughout the editorial process of this paper, Paulo Cesar Mattos Dourado de Mesquita and Ana de Fátima Fontenele Urano Carvalho for critically evaluating a previous version of the manuscript, and Marco Túlio Pacheco Coelho for providing interesting suggestions for the final version of the manuscript. We also thank the Instituto Brasileiro do Meio Ambiente e dos Recursos Naturais Renováveis (IBAMA) for granting permission to keep snakes in NUROF-UFC (CTF Nº 480572; LO Nº 011/2004).

An Incidence of Twinning in Taylor's Cantil (*Agkistrodon taylori*) at the Wildlife Conservation Society's Bronx Zoo

Animals in managed care, such as in zoos and aquaria, can provide insights into occurrences rarely observed in the wild. Thus, these institutions have a great potential for contributing biological information to the scientific community. Reproductive behaviors in reptiles, particularly egg-laying and the bearing of live young are infrequently observed in the wild; therefore, observations in captivity can provide insight as to what can be expected within wild populations. Instances of twinning in reptiles have been reported by Derickson (1927), Curtis (1950), List and Smith (1954), Carpenter and Yoshida (1957), Crooks and Smith (1958), Yntema (1971), Singh and Thapliyal (1973), Marion (1980), Eckert (1990), Tucker and Janzen (1997), and Mendyk (2007), but to our knowledge, observations of true twinning in live-bearing snakes are lacking. Here, we report a case of twinning in Taylor's Cantil (*Agkistrodon taylori*).

The Wildlife Conservation Society's Bronx Zoo received a female *A. taylori* from the Abilene Zoo on 20 April 2011. This individual was captive-born at the San Antonio Zoo on 23 June 2005. Upon her arrival at the Bronx Zoo, she was housed off-exhibit in a custom-built wooden enclosure measuring ca. 100 × 75 × 75 cm (L × W × H). During her routine quarantine examination, a radiograph revealed numerous developing embryos, and on 8 June 2011, this snake was observed bearing her young. It was noted at the time of birth that one of the egg sac membranes contained two individuals (Fig. 1). All eight young were individually weighed and measured upon emerging from their egg sac membranes (Table 1), as were three infertile eggs (not reported here). Mean mass of young at the time of birth was 11.65 ± 1.144 g, mean snout–vent length (SVL) was 17.98 ± 0.638 cm, and mean total length was 21.99 ± 0.769 cm. The twins were significantly smaller than the rest of their siblings in both mass and SVL (Mann-Whitney U-test, $P = 0.0455$ and $P = 0.0455$,

Fig. 1. Two neonatal Taylor's Cantils (*Agkistrodon taylori*) in one egg sac at the time of birth. There are two heads within the circled area; one oriented vertically and the other horizontally with the ventral side of the lower jaw facing upward.

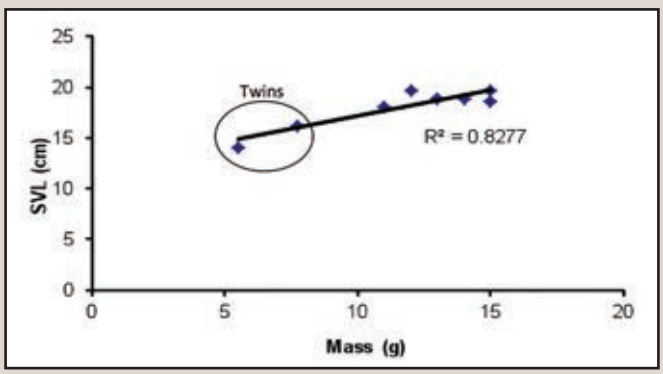

Fig. 2. The mass (g) to SVL (cm) ratios of eight Taylor's Cantils (*Agkistrodon taylori*) at the time of birth; the twins are encircled.

Table 1. Mass (g), snout–vent length (cm), and total length (cm) of Taylor's Cantils (*Agkistrodon taylori*) at time of birth on 8 June 2011. ID#'s H11052 and H11053 represent the two twins.

ID	Mass (g)	Snout–vent length (cm)	Total length (cm)
H11052	7.7	16.2	19.8
H11053	5.5	14.1	17.4
H11054	11.0	18.0	21.9
H11055	12.0	19.7	24.0
H11056	15.0	19.7	24.2
H11057	15.0	18.6	23.0
H11058	14.0	18.8	23.0
H11059	13.0	18.8	22.7

respectively). To determine if the twins were proportionate in size compared to the rest of the clutch, we performed a linear regression. The ratio of mass to SVL does appear to be similar to the remainder of the clutch (Fig. 2; $R^2 = 0.8279$, $P = 0.0017$).

It is unclear whether this occurrence implies identical or fraternal twinning, as we did not identify the presence of a single or double yolk. One twin did not survive long after birth; necropsy detected fluid in the lungs, but there were no apparent developmental deformities. Lack of space in the egg sac and the potential for sharing a yolk appears to impede the growth of embryos during this developmental stage (Marion 1980). Marion (1980) cited several accounts of twins having a combined weight similar to those of single siblings. Since the twins were significantly smaller than their siblings, this could indicate that twins born in the wild may be less fit than non-twin siblings.

Acknowledgments.—We thank the Wildlife Conservation Society's Bronx Zoo Department of Herpetology for their assistance in obtaining the neonate morphometrics. Pat Thomas and Don Boyer reviewed an earlier draft of this manuscript.

HERPETOCULTURE NOTES

SQUAMATA — LIZARDS

***CTENOPHORUS MIRRITYANA* (Barrier Range Dragon). LONGEVITY.** *Ctenophorus mirrityana* is an endangered species of rock-dwelling agamid, currently known only from four locations in western New South Wales, Australia. It was only described in 2013, when it was split from the closely related *C. decresii* (McLean et al. 2013. Rec. Aust. Mus. 65:51–63). Although the longevity of wild *C. mirrityana* is not known, this genus is typically short-lived with the wild lifespan of three studied species recorded at 1–2 years (Cogger 1978. Aust. J. Zool. 26:653–672; Dickman et al. 1999. Oecologia 119:357–366). Despite their short lifespans in the wild, captive individuals may live much longer, with a captive specimen of this species (reported therein as *C. decresii*) previously recorded to live to over 9 years old (McFadden and Harlow 2007. Herpetofauna 37:22–26). Herein we report a captive male *C. mirrityana* that lived for 11 years, 6 months, and 5 days.

The dragon was bred at Taronga Zoo, Sydney, from specimens collected at Mutawintji National Park in 1998 and 1999. It hatched on 22 November 2003. This specimen was housed individually, excluding a period with a post-reproductive female from March 2006 to April 2008, so did not reproduce during its lifetime. It was euthanized on 27 May 2015 due to a decline in mass and body condition, despite remaining active and feeding. Post-mortem examination revealed the dragon had a liver tumor, or biliary adenoma undergoing malignant transformation.

MICHAEL S. McFADDEN and **DEAN PURCELL**, Herpetofauna Division, Taronga Conservation Society Australia, PO Box 20, Mosman, NSW, 2088, Australia (e-mail: mmcfadden@zoo.nsw.gov.au).

SQUAMATA — SNAKES

***HETERODON SIMUS* (Southern Hog-nosed Snake). LONGEVITY.** Longevity is an important factor in any organism's biology. Even though captivity may potentially prolong an animal's "natural" lifespan, information on maximum potential longevity, particularly for species of conservation concern, can be an important consideration when conducting field studies and making management decisions.

A captive longevity record of 12 years and 42 days for *Heterodon simus* was reported by Beane and Thorp (2007. Bull. Chicago Herpetol. Soc. 42[12]:193), who further reported four additional specimens that had exceeded 11 years in captivity, as of that writing. All of those snakes are now deceased. The individual surviving the longest was a male, wild-collected as a recent hatchling in Moore County, North Carolina, USA (7.6 km WSW Pinebluff, 35.0894°N, 79.5514°W; WGS 84) on 17 October 1996 by Jeffrey C. Beane and Laura H. Terry. The snake was maintained in captivity until his death on 10 April 2015. During that period, he was fed mostly laboratory House Mice (*Mus musculus*) and neonatal laboratory Norway Rats (*Rattus norvegicus*). Initially, these were "scented" with Squirrel Treefrogs (*Hyla squirella*),

Green Treefrogs (*H. cinerea*), Pine Woods Treefrogs (*H. femoralis*), or Spring Peepers (*Pseudacris crucifer*). Other food items eaten between 17 October 1996 and 1 February 1998 were *H. femoralis*, *H. squirella*, and cut pieces of chicken (*Gallus gallus*) flesh. The snake first accepted an "unscented" neonatal laboratory mouse on 18 September 1997. From 1 February 1998 until his death, he was fed exclusively laboratory mice and rats. The snake molted 33 times during his captivity (and almost certainly had undergone only one postnatal molt when first collected). During the last few years of his life, he experienced difficulty with ecdysis, developed cataracts in both eyes, and occasionally regurgitated food. During his final months, he had difficulty swallowing even small food items, and occasionally was gently "assisted" with swallowing. On 9 April 2015, the day before his death, he attempted to feed, but was unable to swallow unassisted.

To my knowledge, this period of 18 years, 5 months and 24 days far surpasses all previously reported records for the species. Upon death, the snake measured 379 mm SVL and 485 mm total length. The specimen was maintained under permits issued by the North Carolina Wildlife Resources Commission, and is deposited in the herpetological collection of the North Carolina State Museum of Natural Sciences (NCSM 84567).

JEFFREY C. BEANE, North Carolina State Museum of Natural Sciences, Research Laboratory, MSC # 1626, Raleigh, North Carolina 27699-1626, USA; e-mail: jeff.beane@naturalsciences.org.

Cover Images for *Herpetological Review*

We are looking for photographic images to appear on future covers of *HR*. To be considered, preferred images should have the following qualities:

- Should be technically superior photographs (e.g., composition, lighting, etc., should be excellent; subject must be in focus).
- Should be taken in vertical format, or, if in landscape format, permit cropping to achieve a vertical orientation (2550 × 3300 ppi).
- Should be based on film or digital media; if the latter, the native resolution must be sufficiently high to permit cropping and/or enlargement to print publication quality.
- Preference will be given to images that depict poorly known species. These could include recently described taxa or species for which a color illustration has never been published.
- Preference will be given to images that communicate some aspect of the biology of the organism (e.g., predation, feeding, courtship, crypsis).
- Images should not have been published previously nor concurrently submitted for publication elsewhere (print or electronic media).

Images for consideration should be submitted as low-resolution jpg or pdf files. Do not send full resolution images unless requested to do so. All submissions or questions should be directed to the Editor (herpreview@gmail.com).

GEOGRAPHIC DISTRIBUTION

GYMNOPHIONA — CAECILIANS

***SIPHONOPS PAULENSIS* (Boettger's Caecilian)**. BRAZIL: CEARÁ: Municipality of Crato: ca. 3.5 km SW of Crato (7.279722°S, 39.438250°W; WGS 84). 11 February 2014. Milene G. Gaiotti. Verified by I. J. Roberto. Coleção Herpetológica da Universidade Regional do Cariri, Crato, Ceará, Brazil (URCA-H 7095). *Siphonops paulensis* has a large distribution, from tropical Brazilian rainforest in the southern Amazon basin, to northern Argentina, Paraguay, and eastern Bolivia (Taylor 1968. The Caecilians of the World. A Taxonomic Review. University of Kansas Press, Lawrence, Kansas. 848 pp.). In Brazil, it occurs in the states of Rio de Janeiro, São Paulo, Goiás, Mato Grosso do Sul, Rio Grande do Norte, Rio Grande do Sul, Minas Gerais, Distrito Federal, Ceará, Mato Grosso, Tocantins, Maranhão and Sergipe (Sawaya 1937. Bol. Facul. Fil. Ciên. Letras Univers. SP. 1:225–263; Dunn 1942. Bull. Mus. Comp. Zool. 91:437–540; Dunn 1942. Bull. Mus. Comp. Zool. 91:437–540; Schmidt and Inger 1951. Fieldiana Zool. 31:439–465; Braun and Braun 1980. Iheringia. Sér. Zool. 56:121–146; Kokubum and Menin 2001. Herpetol. Rev. 32:53; Souza et al. 2002. Herpetol. Rev. 33:146–147; Loebmann and Haddad 2010. Biota Neotrop. 10:227–256; Faria and Mott 2011. Herpetol. Notes 4:53–56; Lema and Martins 2011. Anfíbios do Rio Grande do Sul. Catálogo, Diagnose, Distribuição e Iconografia. Ed. Univ. PUCRS. Press, Porto Alegre, Brazil. 196 pp.; Valdujo et al. 2011. Biota. Neotrop. 11:251–262; Maciel et al. 2012. J. Herpetol. 46:47–50; Miranda et al. 2013. Herpetol. Notes 6:327–329; Santana et al. 2015. Check List 11:1531–1533). This new record fills the gap in the distribution between Ibiapaba Municipality (Ceará State), and Simão Dias Municipality (Sergipe State; Loebmann and Haddad 2010, *op. cit.*; Santana et al. 2015, *op. cit.*) and is the first record from Chapada do Araripe in northeastern Brazil. The new record extends the distribution ca. 300 km SE from the Planalto da Ibiapaba, Ceará and ca. 400 km NW from Simão Dias, Sergipe.

CAUDATA — SALAMANDERS

***AMBYSTOMA JEFFERSONIANUM* (Jefferson Salamander)**. USA: INDIANA: Scott Co.: Clark State Forest (38.642740°N, 85.885825°W; NAD 83). 1 April 2015. Sarabeth Klueh-Mundy and Jason Mirtl. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2015ao, photo voucher). This capture provides a new county record for Indiana (Minton 2001. Amphibians and Reptiles of Indiana. Indiana Academy of Science, Indianapolis, Indiana. 404 pp.).

SARABETH KLUEH-MUNDY (e-mail: sklueh-mundy@dnr.IN.gov) and **JASON MIRTL**, Wildlife Science Unit, Indiana Department of Natural Resources, Division of Fish and Wildlife, 5596 East State Road 46, Bloomington, Indiana 47401, USA.

***AMBYSTOMA MACULATUM* (Spotted Salamander)**. USA: ALABAMA: Sumter Co.: CR 85, ~3.83 road km N of AL 116 (32.84188°N, 88.19707°W; WGS 84). 21 March 2015. Brian D. Holt and Evan Lawrence. Verified by David Laurencio. Auburn University Natural History Museum (AUM AHAP-D 961, digital photographic voucher). New county record (Mount 1975. Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University, Alabama. 347 pp.). One adult observed crossing road during light rain. The nearest previously documented locations in the state occur in Pickens Co. to the north (Mount 1975, *op. cit.*) and Greene Co. to the east. This record fills a gap in the Southeastern Floodplains and Low Terraces section of the Southeastern Plains ecoregion in western Alabama.

Thanks to Eric Soehren for reviewing this note and David Laurencio for verifying the identification and confirming the county record. Additional online museum records were examined for county occurrences via VertNet.

BRIAN D. HOLT (e-mail: brian.holt@dcnr.alabama.gov) and **EVAN LAWRENCE**, Alabama Department of Conservation and Natural Resources, State Lands Division, Natural Heritage Section, 64 N Union Street, Suite 464, Montgomery, Alabama 36130, USA.

***AMBYSTOMA MACULATUM* (Spotted Salamander)**. USA: TENNESSEE: Grainger Co.: 7.5 km W of New Market (36.1072°N, 83.6365°W; WGS 84). 19 February 2011. Lynn F. Faust. Verified by Floyd A. Scott. David H. Snyder Museum of Zoology, Austin Peay State University (APSU 19480, color photo). New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions, the latter [http://www.apsu.edu/amatlas/, accessed 9 March 2015] including links to data on amphibians in Tennessee that have appeared since 1996). A single individual was found under a small log near a vernal pool on McBee Island along the Holston River.

MARTIN K. WOOD (e-mail: woodvflwfs@gmail.com) and **TED M. FAUST**, Clinch River Environmental Studies Organization (CRESO), Clinton, Tennessee 37716, USA (e-mail: tmfaust21@gmail.com).

***AMBYSTOMA OPACUM* (Marbled Salamander)**. USA: TENNESSEE: Grainger Co.: 7.5 km W of New Market (36.1072°N, 83.6365°W; WGS 84). 13 November 2010. Lynn F. Faust. Verified by A. Floyd Scott. David H. Snyder Museum of Zoology, Austin Peay State University (APSU 19479, color photo). New county

record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions, the latter [http://www.apsu.edu/amatlas/, accessed 9 March 2015] including links to data on amphibians in Tennessee that have appeared since 1996). A single individual was found under a piece of bark near a vernal pool on McBee Island. The individual was surrounded by eggs.

MARTIN K. WOOD (e-mail: woodvflwfs@gmail.com) and **TED M. FAUST**, Clinch River Environmental Studies Organization (CRESO), Clinton, Tennessee 37716, USA (e-mail: tmfaust21@gmail.com).

***AMPHIUMA TRIDACTYLUM* (Three-toed Amphiuma)**. USA: ALABAMA: Dallas Co.: 0.34 mi WSW of AL 14 along train tracks (32.42926°N, 86.95938°W; WGS 84). 30 June 2013. C. Davis. Auburn University Museum of Natural History (AUM 40446). Verified by David Laurencio. New county record (Mount 1996. The Reptiles and Amphibians of Alabama. University of Alabama Press. xi+347 pp.). *Amphiuma tridactylum* is assumed to occur throughout the western half of the state; however, verified records are lacking for many Alabama counties. Specimen collected with a baited funnel trap. Specimen collected under an Alabama Department of Conservation and Natural Resources permit (#2014044694668680) issued to CKW and CWD.

CHRIS W. DAVIS, Auburn University at Montgomery, Montgomery, Alabama 36124-4023, USA (e-mail: cdavis53@aum.edu), **ROGER D. ***ANEIDES AENEUS* (Green Salamander)**. USA: NORTH CAROLINA: Buncombe Co.: Rocky Broad River corridor, 3.4 km airline N town of Bat Cave (location details withheld and on file with the North Carolina Wildlife Resources Commission). 8 May 2015. Lori A. Williams, Alan D. Cameron, Bill McAninch, and Jerry McAninch. Verified by Jeffrey C. Beane. North Carolina Museum of Natural Sciences (NCSM 13183, photo voucher). New county record (NCSM files; Beane et al. 2010. Amphibians & Reptiles of the Carolinas and Virginia, 2nd ed. University of North Carolina Press, Chapel Hill, 274 pp.; North Carolina Natural Heritage Program [NCNHP]. 2015. Biotics Database. Department of Environment and Natural Resources, Raleigh, North Carolina.). Record represents the northernmost known occurrence to date in the greater Bat Cave area and on the western side of the Hickory Nut Gorge in North Carolina (Beane et al. 2010, *op. cit.*; NCNHP, *op. cit.*). Closest previous historical records in the state are from private property, Henderson County, 1.6 km airline S (location details withheld and on file with the North Carolina Wildlife Resources Commission). Juvenile regenerating entire tail (TL = 41.1 mm, SVL = 37.5 mm) temporarily collected during visual encounter surveys of rock outcrops.

***NOTOPHTHALMUS VIRIDESCENS* (Eastern Newt)**. USA: ALABAMA: Pickens Co.: Coal Fire Creek at AL 17, approximately 7.15 road km S of intersection with AL 96 (33.51627°N, 87.98272°W; WGS 84). 3 March 2015. Ashley Peters and Brian D. Holt. Verified by David Laurencio. Auburn University Natural History Museum (AUM AHAP-D 917, digital photographic voucher). New county record (Mount 1975. Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University, Alabama. 347 pp.). Three adults, two of which were in amplexus, were observed in a ditch filled with overflow from Coal Fire Creek. Previously documented locations in the state occur in Lamar County to the north (Graham et al. 2009. Herpetol. Rev. 40:367–371), Tuscaloosa County to the east, and Greene County to the south (Mount 1975, *op. cit.*). This record fills a gap in the Fall Line Hills of the Southeastern Plains ecoregion in western Alabama.

We thank Eric Soehren for reviewing this note and David Laurencio for verifying the identification and confirming the county record. Additional online museum records were examined for county occurrences via VertNet.

BRIAN D. HOLT (e-mail: brian.holt@dcnr.alabama.gov), and **ASHLEY PETERS**, Alabama Department of Conservation and Natural Resources, State Lands Division, Natural Heritage Section, 64 N Union Street, Suite 464, Montgomery, Alabama 36130, USA.

***NOTOPHTHALMUS VIRIDESCENS* (Eastern Newt)**. USA: INDIANA: Lawrence Co.: Hoosier National Forest (38.737985°N, 86.581768°W; NAD 83). 9 May 2015. Amy Kearns, Noah Kearns, and Sarabeth Klueh-Mundy. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2015an, photo voucher). New county record (Minton 2001. Amphibians and Reptiles of Indiana. Indiana Academy of Science, Indianapolis, Indiana. 404 pp.).

AMY KEARNS, **NOAH KEARNS**, and **SARABETH KLUEH-MUNDY**, Wildlife Science Unit, Indiana Department of Natural Resources, Division of Fish and Wildlife, 5596 East State Road 46, Bloomington, Indiana 47401, USA (e-mail: sklueh-mundy@dnr.in.gov).

ANURA — FROGS

***ACRIS BLANCHARDI* (Blanchard's Cricket Frog)**. USA: WISCONSIN: Adams Co.: ca. 5 miles W of Briggsville (43.655°N, 89.688°W; WGS 84). 22 September 1929. Collector unknown. Verified by K. Tighe. National Museum of Natural History (USNM 311739). New county record that completes a gap in the species' documented range (Casper 1996. Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Milwaukee Publ. Mus., Milwaukee, Wisconsin. 87 pp.). Supplied coordinates have been approximated and are based on the museum specimen's locality description. Given the age of this specimen, it is unknown if this species still resides in the general vicinity; however, this specimen provides important historical context for the distribution of this species in Wisconsin. *Acris blanchardi* has experienced a range contraction in the state from the 1960s to the 1980s, and is listed as endangered in Wisconsin. Currently, the nearest known Wisconsin population is ca. 20 km to the south. Because the circumstances surrounding the collection of this specimen are unknown, additional effort to re-confirm the presence of this species in Adams Co. is warranted.

ANDREW F. BADJE (e-mail: andrew.badje@wisconsin.gov), **TARA L. BERGESON**, and **RORI A. PALOSKI**, Wisconsin Department of Natural Resources, Bureau of Natural Heritage Conservation, 101 S. ***ACRIS CREPITANS* (Eastern Cricket Frog)**. USA: ALABAMA: Sumter Co.: Approximately 3.83 road km N of AL 116 on CR 85 (32.84188°N, 88.19707°W; WGS 84). 21 March 2015. Brian D. Holt and Evan Lawrence. Verified by David Laurencio. Auburn University Natural History Museum (AUM 41116, 41117). New county record (Mount 1975. Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University, Alabama. 347 pp.). Several individuals observed with *Acris gryllus* (Southern Cricket Frog; AUM 41114, 41115) on road during light rain. The nearest previously documented locations in the state occur in each adjacent county: Greene County to the east (VertNet), Pickens to the north, Marengo to the southeast, and Choctaw to the south (Mount 1975, *op. cit.*). This record fills a gap in the Southeastern Floodplains and Low Terraces section of the Southeastern Plains ecoregion in western Alabama.

Thanks to Eric Soehren for reviewing this note and David Laurencio for verifying the identification and confirming the county record. Additional online museum records were examined for county occurrences via VertNet.

BRIAN D. HOLT (e-mail: brian.holt@dcnr.alabama.gov) and **EVAN LAWRENCE**, Alabama Department of Conservation and Natural Resources, State Lands Division, Natural Heritage Section, 64 N Union Street, Suite 464, Montgomery, Alabama 36130, USA.

***ANAXYRUS AMERICANUS* (American Toad)**. USA: INDIANA: Noble Co.: Crooked Lake (41.268266°N, 85.480650°W; WGS 84). 23 June 2015. Andrew Hoffman and Sierra Hoffman. Verified by Kenneth Krysko. Florida Museum of Natural History (UF 175751, photo voucher). New county record (Minton 2001. Amphibians and Reptiles of Indiana. Indiana Academy of Science, Indianapolis, Indiana. 404 pp.). Numerous recently metamorphosed toads found near lake shore in grass.

ANDREW HOFFMAN (e-mail: hoffmana10@alumni.hanover.edu) and **SIERRA HOFFMAN** Terre Haute, Indiana 47803, USA (e-mail: sshepard1@sycamores.indstate.edu).

***ANAXYRUS AMERICANUS* (American Toad)**. USA: TENNESSEE: Hardin Co.: Horse Creek Wildlife Sanctuary and Animal Refuge (35.123433°N, 88.167761°W; WGS 84). 30 April 2015. Lee J. Barton, Brian P. Butterfield, Paige Whittaker, and Joshua P. Kee. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19549, color photo). First record for Hardin County (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions [http://www.apsu.edu/amatlas/]. Accessed 2 May 2015). Calling male was captured by hand. Voucher collected under Tennessee Wildlife Resources Agency Permit 1494.

LEE J. BARTON, **BRIAN P. BUTTERFIELD** (e-mail: bbutterfield@fhu.edu), and **PAIGE WHITTAKER**, Freed-Hardeman University, 151 E. Main Street, Henderson, Tennessee 38340, USA; **JOSHUA P. KEE**, Department of Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA.

***CALLUELLA FLAVA* (Yellow Burrowing Frog)**. BRUNEI DARUSSALAM: TEMBURONG: Amo District: Ulu Temburong National Park, low ridge between Sungei Temburong and Sungei Apan (4.55762°N, 115.15099°E; WGS 84), 120 m elev. 25 November 2012. Hanyrol H. Ahmad Sah. Verified by Samuel Shonleben. Universiti Brunei Darussalam Natural History Museum (UBDM 2.00199). Female, on ridge (presumably drier, sandy soil) of lowland mixed-dipterocarp forest in plastic bucket pitfall trap (SVL 37.2 mm; with eight large ova). Bucket filled with 5 cm of water as result of heavy rain. Extends previous single record from Kerangas Forest between Camp 5 and Sungei Berrar, Gunung Mulu National Park, Sarawak, Malaysia (Kiew 1984. Malayan Nat. J. 37:163–166) by 54 km to the northeast. First record for Brunei Darussalam and second record for species. Permit No. UBD/KBFSC/R/2.

HANYROL H. AHMAD SAH (e-mail: spanish_novia@yahoo.co.uk) and **T. ULMAR GRAFE**, Faculty of Science, Universiti Brunei Darussalam, Gadong, BE1410, Brunei Darussalam (e-mail: ulmar.grafe@ubd.edu.bn).

***CRAUGASTOR BRANSFORDII* (Bransford's Robber Frog)**. REPUBLIC OF PANAMA: VERAGUAS: Santa Fe District: Guayabito River (8.54719°N, 81.02581°W; WGS 84), 633 m elev. 25 July 2014. E. E. Flores. Verified by Andreas Hertz. Museo de Vertebrados, Universidad de Panamá, Panama City, Panama (MVUP 2483). This report vouchers for the first time the presence of this species in Veraguas Province and in the Santa Fe National Park and extends the known range of the species in Panama 48 km to the east of Fortuna Forest Reserve in Chiriqui Province (NMNH 572226.6567807), and 50 km to the west of El Cope National Park in Cocle Province (NMNH 572221.6567800). The frog was captured at 1835 h on rain forest leaf litter near the river's bank. This work was conducted under the scientific permit (SE/A-114-13) provided by the Panamanian National Authority for the Environment (ANAM).

***DENDROPSOPHUS MICROCEPHALUS* (Small-headed Treefrog)**. NICARAGUA: CHINANDEGA: Comarca Las Grietas, Finca San José de las Marías (12.73027°N, 86.86583°W; WGS 84), 25 m elev. 1 September 2012. Javier Sunyer and Pedrarias Dávila. Verified by Lenin A. Obando. Museo Herpetológico de la Universidad Nacional Autónoma de Nicaragua-León, León, Nicaragua (MHUL 163). First record for Chinandega, with the closest known locality ca. 65 km northeast at Estelí (Köhler 2001. Anfibios y Reptiles de Nicaragua. Herpeton, Verlag Elke Köhler, Offenbach, Germany. 208 pp.). The frog was calling at night on grass that emerged from a seasonal pond in a pasture carved from lowland dry forest (Holdridge 1967. Life Zone Ecology. Tropical Science Center, San José, Costa Rica. 206 pp.). The frog was caught under permit No. 002–012012 issued by Ministerio del Ambiente y los Recursos Naturales, Managua, Nicaragua.

JAVIER SUNYER (e-mail: jsunyermaclennan@gmail.com) and **PEDRARIAS DÁVILA**, Museo Herpetológico de la UNAN-León (MHUL), Departamento de Biología, Facultad de Ciencias y Tecnología, Universidad Nacional Autónoma de Nicaragua-León, León, Nicaragua; **LILIANA SOLANO**, Computational Evolutionary Biology, Faculty of Life Sciences, University of Manchester, Manchester, M13 9PT, United Kingdom.

***ELEUTHERODACTYLUS PLANIROSTRIS* (Greenhouse Frog)**. USA: MISSISSIPPI: Hinds Co.: Jackson (32.31342°N, 90.16976°W; WGS 84). 11 June 2014. Wenhua Lu, Tom Mann, and Debora L. Mann. Verified by Robert L. Jones. Mississippi Museum of Natural Science (MMNS 10386). New county record. Introduced species previously recorded in Mississippi from a greenhouse in Oktibbeha Co., Starkville (about 180 km to the NE), from Harrison Co., Gulfport (about 238 km to the SE; Dinsmore 2004. Herpetol. Rev. 35:403), and Jackson Co., Ocean Springs (Jennifer Y. Lamb, pers. comm.). Five or six individuals were calling from a wooded ravine in the Belhaven residential neighborhood of Jackson. One was calling from leaf of a shrub at a height of approximately 1 m.

A survey for calling frogs was undertaken on the night of 14 June 2014. The species was heard at the collection site and 7 other locations within 1 km. An additional specimen (MMNS 10475) was collected on 29 August 2014, approximately 3 km from the Belhaven collection site; others were heard calling nearby.

The presence of the frogs in multiple locations over a distance of at least 3 km suggests that the species is established in Jackson. This represents the most northerly inland population established outdoors of which we are aware. The population survived a cold winter: the US National Weather Service recorded 62 days between October 2013 and April 2014 when the temperature reached 0°C or lower in Jackson (National Weather Service, Jackson, MS Weather Forecast Office. http://www.srh.noaa.gov/jan/?n=climate_zone_jan_90_100_degs, updated 12 September 2014, accessed 12 September 2014). The means of introduction is not known; the Gulfport population is suspected to have arrived on nursery stock (Dinsmore 2004, *op. cit.*).

DEBORA L. ***GASTROPHRYNE CAROLINENSIS* (Eastern Narrow-mouthed Toad)**. USA: ALABAMA: Tallapoosa Co.: Coon Creek Forever Wild Tract, Coon Creek Landing Road approximately 1.05 road km N of intersection with Gravel Pit Drive (32.59706°N, 85.88016°W; WGS 84). 22 May 2014. Brian D. Holt, Betsy Battistella, and Kevin Carr. Verified by David Laurencio. Auburn University Natural History Museum (AUM AHAP-D 967, digital photographic voucher). New county record (Mount 1975. Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University, Alabama. 347 pp.). One adult observed under hardwood log upslope from floodplain at mouth of Coon Creek. The nearest previously documented locations in the state occur in Chambers Co. to the northeast, Lee Co. to the east, and Macon Co. to the south (Mount 1975, *op. cit.*). This record fills a gap in the Southern Outer Piedmont section of the Piedmont ecoregion in east-central Alabama.

Thanks to Eric Soehren for reviewing this note and David Laurencio for verifying the identification and confirming the county record. Additional online museum records were examined for county occurrences via VertNet.

BRIAN D. HOLT, Alabama Department of Conservation and Natural Resources, State Lands Division, Natural Heritage Section, 64 N Union Street, Suite 464, Montgomery, Alabama 36130, USA (e-mail: brian.holt@dcnr.alabama.gov); **BETSY BATTISTELLA**, 331 Funchess Hall, Auburn University, Auburn, Alabama 36849, USA; **KEVIN CARR**, 2313 Windsor Ave, Montgomery, Alabama 36107, USA.

HYALINOBATRACHIUM MONDOLFII. BRAZIL: PARÁ. Municipality of Vitória do Xingu: 24 km NNW of Altamira (2.971°S, 52.277°W; WGS 84). 22 January 2014. E. A. Oliveira and J. Carvalho. Verified by J. C. Señaris. Laboratório de Zoologia de Altamira, Altamira, Pará, Brazil (LZA 841, 844). Previously known from Amazonian areas of Venezuela, Bolivia, and Colombia (Castroviejo-Fisher et al. 2011. Zootaxa 3132:1–55). From Brazil it is known from Para State, Óbidos, north of the Amazon River (Avila-Pires et al. 2010. Bol. Mus. Para. Emílio Goeldi. 5:13–112 [reported as *Cochranella* sp.]) and Acre State, Municipality of Feijó, on the left bank of the Jurupari River (8°9'S, 70°21'W) (Venâncio et al. 2014. Check List 10:1184–1186). Southeasternmost record for the species, extends known distribution 490 km from Óbidos (Avila-Pires et al., *op. cit.*) the nearest locality previously known.

We thank SISBIO/Brazil for the permit for collection of biological material (#32401).

ELCIOMAR ARAÚJO DE OLIVEIRA, Instituto Nacional de Pesquisas da Amazônia – INPA, Programa de Pós-graduação em Genética, Conservação e Biologia Evolutiva – GCBEv, Av. ***LEPTOPELIS MACKAYI* (Mackay's Forest Treefrog)**. DEMOCRATIC REPUBLIC OF CONGO: ORIENTALE PROVINCE: Toyokana (2.02734°N, 30.06653°E, WGS84, elev. 1294 m). 31 December 2014. Lodjo (2.20135°N, 30.06653°E; WGS84), elev. 1220 m. 4 January 2015. Chifundera Kusamba, Mwenebatu M. Aristote, Wandege M. Moninga, and Franck M. Masudi. Verified by S. Lötters. University of Texas at El Paso Biodiversity Collections (UTEP 21170–71). Collected on vegetation in secondary, transitional forest during opportunistic visual searches in the evening. New country record (Köhler et al. 2006. Herpetol. J. 16:183–189), extending the distribution ca. 550 km WNW from the type locality at Kakamega Forest, western Kenya, the only known locality for the species.

ELI GREENBAUM (e-mail: egreenbaum2@utep.edu) and **DANIEL F. HUGHES**, Department of Biological Sciences, University of Texas at El Paso, 500 W. University Ave., El Paso, Texas 79912, USA; **CHIFUNDERA KUSAMBA**, Laboratoire d'Herpétologie, Département de Biologie, Centre de Recherche en Sciences Naturelles, Lwiro, République Démocratique du Congo; **FRANCK M. MASUDI**, Université de Kisangani, Centre de Surveillance de la Biodiversité (DEBRT), B.P. 2012 Kisangani, République Démocratique du Congo.

***LITHOBATES AREOLATUS* (Crawfish Frog)**. USA: ALABAMA: Sumter Co.: in the vicinity of Gainesville (location information withheld and on file with the Alabama Department of Conservation and Natural Resrouces). 10 March 2015. Brian D. Holt. Verified by David Laurencio. Auburn University Natural History Museum (AUM AHAP-C 52, audio recording). New state record (Mount 1975. Reptiles and Amphibians of Alabama. Agricultural

Experiment Station, Auburn University, Alabama. 347 pp.). Several individuals heard calling for a stretch of approximately 3.21 km along the south side of roadway. A second location was discovered on 11 March 2015 (AUM AHAP-C 53, audio recording) approximately 18.62 air km S of the first location. Individuals were calling east and west of this site for a stretch of approximately 1.21 km. The nearest previously documented location occurs in Winston Co., Mississippi. These records extend the previously accepted range of *L. areolatus* to the southeast into the Blackland Prairie section of the Southeastern Plains ecoregion in western Alabama.

This species appears to be in decline throughout much of its range (Dodd 2013. Frogs of the United States and Canada. Johns Hopkins University Press, Baltimore, Maryland. 982 pp.) and is expected to receive Priority 1 status for the state (Mark Bailey, *in litt.*). Priority 1 status is defined as taxa critically imperiled and at risk of extinction/extirpation because of extreme rarity, restricted distribution, decreasing population trend/population viability problems, and specialized habitat needs/habitat vulnerability due to natural/human-caused factors (Mirarchi 2004. Alabama Wildlife. Volume 1. A Checklist of Vertebrates and Selected Invertebrates: Aquatic Mollusks, Fishes, Amphibians, Reptiles, Birds, and Mammals. University of Alabama Press, Tuscaloosa. 209 pp.).

Thanks to Eric Soehren for reviewing this note and David Laurencio and Mark Bailey for verifying the identification. Additional online museum records were examined for county occurrences via VertNet.

BRIAN D. HOLT, Alabama Department of Conservation and Natural Resources, State Lands Division, Natural Heritage Section, 64 N Union Street, Suite 464, Montgomery, Alabama 36130, USA; e-mail: brian.holt@dcnr.alabama.gov.

***LITHOBATES AREOLATUS* (Crawfish Frog)**. USA: ILLINOIS: Gallatin Co.: pond in pasture, 25 m E of Shain Cemetery Road, 0.3 km N of U.S. Route 45 (37.901839°N, 88.369745°W; WGS 84). 13 March 2015. John G. Palis and Erin L. Palmer. Verified by Christopher A. Phillips. Illinois Natural History Survey (INHS 43259, photo voucher). First record for county, filling gap between Saline and White Counties (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Natural History Survey. Manual 8, Champaign, Illinois. 282 pp.). Gravid adult female observed with vocalizing males at 2145 h.

JOHN G. PALIS, P.O. Box 387, Jonesboro, Illinois 62952, USA, e-mail: jpalis@yahoo.com.

***LITHOBATES CATESBEIANUS* (American Bullfrog)**. USA: ALABAMA: Sumter Co.: AL 116, approximately 4.84 road km E of AL 17 (32.81076°N, 88.26282°W; WGS 84). 10 March 2015. Brian D. Holt. Verified by David Laurencio. Auburn University Natural History Museum (AUM AHAP-D 959, digital photographic voucher). New county record (Mount 1975. Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University, Alabama. 347 pp.). One adult observed at the edge of a roadside ditch. The nearest previously documented locations in the state occur in Greene Co. to the east and Choctaw Co. to the south (Mount 1975, *op. cit.*). This record fills a gap in the Blackland Prairie of the Southeastern Plains ecoregion in western Alabama.

Thanks to Eric Soehren for reviewing this note and David Laurencio for verifying the identification and confirming the county record. Additional online museum records were examined for county occurrences via VertNet.

BRIAN D. HOLT, Alabama Department of Conservation and Natural Resources, State Lands Division, Natural Heritage Section, 64 N Union Street, Suite 464, Montgomery, Alabama 36130, USA, e-mail: brian.holt@dcnr.alabama.gov.

***LITHOBATES CATESBEIANUS* (American Bullfrog)**. USA: INDIANA: Noble Co.: Crooked Lake (41.268903°N, 85.482217°W; WGS 84). 23 June 2015. Andrew Hoffman and Sierra Hoffman. Verified by Kenneth Krysko. Florida Museum of Natural History (UF 175750, photo voucher). New county record (Minton 2001. Amphibians and Reptiles of Indiana. Indiana Academy of Science, Indianapolis, Indiana. 404 pp.). Large, adult female found in shallows of lake. Multiple adults heard calling from the lake that night.

ANDREW HOFFMAN (e-mail: hoffmana10@alumni.hanover.edu) and **SIERRA HOFFMAN**, Terre Haute, Indiana 47803, USA (e-mail: sshepard1@sycamores.indstate.edu).

***LITHOBATES CATESBEIANUS* (American Bullfrog)**. USA: TENNESSEE: Hardin Co.: Horse Creek Wildlife Sanctuary and Animal Refuge (35.12005°N, 88.178636°W; WGS 84). 30 April 2015. Brian P. Butterfield, Lee J. Barton, Eli Todd, and Kyle Robertson. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19550, color photo). First record for Hardin County (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions [http://www.apsu.edu/amatlas/]. Accessed 2 May 2015). Calling male was captured by hand. Voucher collected under Tennessee Wildlife Resources Agency Permit 1494.

BRIAN P. BUTTERFIELD (e-mail: bbutterfield@fhu.edu), **LEE J. BARTON**, **ELI TODD**, and **KYLE ROBERTSON**, Freed-Hardeman University, 151 E. Main Street, Henderson, Tennessee 38340, USA.

***LITHOBATES FORRERI* (Forrer's Leopard Frog)**. MÉXICO: SONORA: Municipality of Hermosillo: 21 km NE of Hermosillo (29.20267°N, 110.78407°W; WGS 84), 258 m elev. 27 August 2014. J. H. Valdez-Villavicencio and A. Peralta-García. Verified by James C. Rorabaugh. San Diego Natural History Museum (SDSNH HerpPC 5284, 5285, photo vouchers). First municipality record and the northernmost record for the species in Sonora, extending the range ca. 126 airline km N from the closest known locality, 16 km NE of Guaymas (UIMNH 32067, 32068). The frog was found active between 1930 h and 2100 h near a cattle pond along with five other individuals.

***SCAPHIOPUS HOLBROOKI* (Eastern Spadefoot Toad)**. USA: FLORIDA: Hamilton Co.: Suwanee Ridge Mitigation Park Wildlife and Environmental Area (30.44366°N, 83.04613°W; WGS 84). 3 June 2014. Cody D. Godwin. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 173690, digital photographic voucher). First verified record for Hamilton Co. (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida, Final report, Florida Fish and Wildlife Conservation Commission, Tallahassee, Florida. 524 pp.). Juvenile trapped in funnel trap along drift fence in sandhill habitat.

CODY D GODWIN (e-mail: codydg1dwin@gmail.com), **JONATHN D. MAYS**, and **KEVIN M. ENGE**, Florida Fish and Wildlife Conservation Commission, 1105 S.W. Williston Road, Gainesville, Florida 32601, USA.

***SCINAX NASICUS* (Lesser-snouted Treefrog)**. BRAZIL: RIO DE JANEIRO: Municipality of Porto Real: Porto Real (22.42°S, 44.28°W; SAD 69). 17 November 2013. J. Pederassi. Verified by U. Caramaschi. Museu Nacional, Rio de Janeiro, Brazil (MNRJ 87535–87537). This species is known to occur in Bolivia, Paraguay, Uruguay, Argentina, and in Brazil it occurs in the states of Mato Grosso, Mato Grosso do Sul, southern Goiás, western Minas Gerais, São Paulo, Paraná, Santa Catarina, and Rio Grande do Sul. This species has never been recorded east of Serra da Mantiqueira or closer than 230 km from the Atlantic Ocean (Natale and Herrera 2006. Herpetol. Rev. 37:360; Carezzano and Cabrera 2010. Check List 6:390–391; IUCN 2013. Red List of Threatened species. Version

2013.2. http://www.iucnredlist.org/details/55980/0; Frost 2014. Amphibian Species of the World: an Online Reference. Version 6.0. http://research.amnh.org/vz/herpetology/amphibia/). First state record, extending its occurrence beyond the Mantiqueira Ridge by at least 160 km SE from the nearest locality in Minas Gerais (Municipality of Alfenas), representing the nearest occurrence to the Atlantic Ocean in an area formerly considered part of the Floresta Atlântica domain, but that is now climatically more similar to Cerrado domains because of deforestation. Specimens were collected under a permit (#45308-2) from Sistema de Autorização e Informação em Biodiversidade - SISBIO.

TESTUDINES — TURTLES

***CHELONIA MYDAS* (Green Sea Turtle)**. USA: LOUSIANA: Vermilion Parish: salt marsh bayou approximately 8.5 km S of Louisiana State Hwy 82, near the eastern end of Rockefeller Wildlife Refuge (29.591119°N, 93.559816°W; WGS 84). 5 May 2015. Will Selman, William Strong, Jordan Donini, and Willis Sylvest. Verified by Jeff Boundy. Florida Museum of Natural History (UF 175627, photo voucher). New parish record (Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge, Louisiana. 300 pp.; Selman et al. 2014. Herpetol. Rev. 45:89). This is the second inland record for *C. mydas* in southwestern Louisiana. The individual was located approximately 130 km E of the Cameron Parish record from 2013 (UF 170048). Similar to the Cameron Parish record and others recently reported (St. Bernard Parish: UF 171444; Terrebonne Parish: UF171449; Selman et al. 2014, *op. cit.*), this juvenile individual (~30 cm midline carapace length [MCL]) was live-captured in a fyke net while sampling for *Malaclemys terrapin* (Diamondback Terrapin) under similar environmental conditions (water depth = 1.82 m, bayou width = 22.6 m, salinity = 22.5 ppt, water temperature = 23.7°C). All recent inland records have been juveniles (≤ 30 cm MCL) and have been captured in brackish-salt marshes between late April and mid-May.

WILL SELMAN (e-mail: wselman@wlf.la.gov) and **WILLIAM STRONG**, Rockefeller Wildlife Refuge, Louisiana Department of Wildlife and Fisheries, 5476 Grand Chenier Hwy, Grand Chenier, Louisiana 70643, USA; **JORDAN DONINI**, Department of Biological Sciences, Southeastern Louisiana University, 808 North Pine Street, Hammond, Louisiana 70402, USA; **WILLIS SYLVEST**, Harold and Pearl Dripps Department of Agricultural Sciences, McNeese State University, Lake Charles, Louisiana 70609, USA.

***CHELYDRA SERPENTINA* (Snapping Turtle)**. USA: MINNESOTA: Saint Louis Co.: Hwy 44 (47.24513°N, 91.86366°W; NAD 83). 29 May 2015. Madaline M. Cochrane, Lucas J. O'Neil, Katelin M. Goebel, Stephen D. Nelson. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2015aq, photo voucher). New county record, replaces unvouchered sighting record (Moriarty and Hall 2014. Amphibians and Reptiles in Minnesota. University of Minnesota Press, Minneapolis, Minnesota. 370 pp.). Adult DOR (260 mm straight line carapace length, 97 mm body depth). No vehicle-induced shell damage; flesh consumed prior to collection.

MADALINE M. COCHRANE (e-mail: cochr081@umn.edu) and **RON A. MOEN**, Natural Resources Research Institute, University of Minnesota-Duluth, 5013 Miller Trunk Highway, Duluth, Minnesota 55811, USA; **DONALD J. BROWN**, Department of Forest and Wildlife Ecology, University of Wisconsin-Madison, 1630 Linden Drive, Madison, Wisconsin 53706, USA.

***CHELYDRA SERPENTINA* (Snapping Turtle)**. USA: TEXAS: Guadalupe Co.: ca. 0.13 km E of Old Seguin Road (29.791199°N, 97.935246°W; WGS 84). 10 June 2015. Ivana Mali, Andrea Villamizar-Gomez, and Shashwat Sirsi. Verified by Carl J. Franklin. University of Texas Arlington Amphibian and Reptile Diversity Research Center (UTADC 8532–8535, photo voucher). New county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 447 pp.). This record fills in the distributional gap within the surrounding counties of Bexar, Comal, Hays, and Gonzales, with the exception of Wilson and Caldwell counties (Dixon 2013, *op. cit.*). One juvenile specimen (carapace length: 143 mm; 798 g) captured using a hoopnet trap in a private pond. Specimen (MF37533) was secured under a Scientific Permit for Research (SPR-0102-191) issued to Michael R. J. Forstner by the Texas Parks and Wildlife Department.

ANDREA VILLAMIZAR-GOMEZ (e-mail: a_v118@txstate.edu), **IVANA MALI**, **SHASHWAT SIRSI**, and **MICHAEL R. J. FORSTNER**, Department of Biology, Texas State University, 601 University Drive, San Marcos, Texas 78666, USA.

***MESOCLEMMYS HELIOSTEMMA* (Amazon Toad-headed Turtle)**. BRAZIL: AMAZONAS: Municipality of Jutaí: right margin of Jutaí River, at the Jutaí River Extractive Reserve (3.270745°S, 67.324521°W; WGS 84). 20 May 2014. T. Q. Morcatty. Verified by J. Valsecchi. Coleção Herpetológica do Instituto de Desenvolvimento Sustentável Mamirauá (HERPETO 0717). Specimen collected in tropical upland forest by hand. Municipality of Maraã: Juá Grande stream, at the Amanã Sustainable Development Reserve (2.463195°S, 64.846692°W; WGS 84). 16 February 2014. I. V. Debien and T. Q. Morcatty. Verified by J. Valsecchi. HERPETO 0718. Specimen collected in tropical upland forest with a pitfall trap. Originally, the distribution of *M. heliostemma* was restricted to a small area between the north of Ecuador and Peru and the southern end of Venezuela (McCord et al. 2001. Rev. Biol. Trop. 49:715–764). In 2012, based on a revision of few museum specimens, the species occurrence was confirmed in some parts of Brazil, on the edge of the Amazon rainforest, in the states of Roraima, Amazonas, Pará, Mato Grosso, Rondônia, and Acre (Molina et al. 2012. Zootaxa 3575:63–77). For both new records, the previously known closest record is in Rio Baría, Venezuela (McCord et al. 2001, *op. cit.*), which is 391 kilometers NW from the specimen collected in Maraã and 475 kilometers NE from the specimen collected in Jutaí. Based on these two new records, the distribution of *M. heliostemma* is extended to the central Amazon region, filling a gap of around 1,800,000 km^2 with no previous records. *Mesoclemmys heliostemma* is an inhabitant of temporary pools of upland forest situated near the headwaters of Amazon streams, and the nocturnal habits of the species hampers its collection. These specimens were collected under licences (SISBIO 43620-1 and SISBIO 40358-4) approved by the Instituto Chico Mendes de Conservação da Biodiversidade.

THAÍS Q. MORCATTY (e-mail: tatamorcatty@yahoo.com.br) and **IURY V. D. COBRA**, Instituto de Desenvolvimento Sustentável Mamirauá, Caixa Postal 38, CEP 69553-225, Tefé, Amazonas, Brazil (e-mail: repteis1@gmail.com).

***MESOCLEMMYS RANICEPS* (Black-lined Toad-headed Turtle).** BRAZIL: AMAZONAS: Municipality of Jutaí: left margin of Jutaí River (3.988056°S, 67.826666°W; WGS 84). 14 June 2014. T. Q. Morcatty. Verified by J. Valsecchi. Coleção Herpetológica do Instituto de Desenvolvimento Sustentável Mamirauá, Tefé, Amazonas, Brazil (HERPETO 0716). Specimen collected with a trammel net. *Mesoclemmys raniceps* is expected to occur in the Amazon basin (Bour and Zaher 2005. Pap. Avul. Zool. 45:295–311), including in Peru, Colombia, Venezuela, Bolivia, and Brazil. However, most of the records for the Brazilian Amazon are sparse and old, and some identification problems with the records make it difficult to determine the exact distribution of this species (Iverson 1992. A Revised Checklist with Distribution Maps of the Turtles of the World. Privately printed, Richmond, Indiana. 363 pp.). In Brazil, the species occurs in the states of Amazonas, Roraima, Acre, Pará, and Mato Grosso (Iverson 1992, *op. cit.*). This new record confirms the presence of this species in poorly known areas of central Amazon, covering a gap of 500 km between the two previously documented records. The previous records nearest to the new record are located 253 km NE, in the region of the mouth of the Juruá River, and 257 km SW, in the city of Tabatinga (Iverson 1992, *op. cit.*). Specimen collected under permits (SISBIO 43620-1) granted by Instituto Chico Mendes de Conservação da Biodiversidade.

THAÍS Q. MORCATTY, Instituto de Desenvolvimento Sustentável Mamirauá, Caixa Postal 38, CEP 69553-225, Tefé, Amazonas, Brazil; e-mail: tatamorcatty@yahoo.com.br

***PSEUDEMYS CONCINNA* (River Cooter).** USA: TENNESSEE: Hardin Co.: Horse Creek Wildlife Sanctuary and Animal Refuge (35.124275°N, 88.170613°W; WGS 84). 1 May 2015. Brian P. Butterfield, Lee J. Barton, and T. J. Bivins. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19551, color photo). First record for Hardin Co. (Scott and Redmond 2008 [latest update: 27 October 2014]. Atlas of Reptiles in Tennessee. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/, accessed 2 May 2015. Juvenile individual was captured by hand. Voucher collected under an approved Tennessee Wildlife Resources Agency Permit (#1494).

BRIAN P. BUTTERFIELD (e-mail: bbutterfield@fhu.edu), **LEE J. BARTON**, and **T. J. BIVINS**, Freed-Hardeman University, 151 E. Main Street, Henderson, Tennessee 38340, USA.

***PSEUDEMYS CONCINNA FLORIDANA* (Coastal Plain Cooter).** USA: ALABAMA: Bullock Co.: near intersection of Reeder Branch and Highway 51 west of Hurtsboro, AL (32.23175°N, 85.45277°W; WGS 84). 17 May 2015. Roger Birkhead, Chelsea Ward, Michael Birkhead, Sawyer Birkhead and Adelaide Birkhead. Verified by Craig Guyer and David Laurencio. Auburn University Natural History Museum (AUM-O 4875). New county record (Mount 1996. The Reptiles and Amphibians of Alabama. University of Alabama Press. 347 pp.). In addition to Mount (1996), VertNet and AUM holdings were searched 3 June 2015. Adult female with a straight line carapace length of 28.0 cm collected DOR. Skeletal specimen and DNA sample taken.

Pseudemys c. floridana is assumed to occur primarily in the southern tier of counties of the state encompassing the Southern Pine Hills and Dougherty Plain physiographic regions (Mount 1996, *op cit.*). This specimen extends the range of *P. c. floridana* northward into the Black Prairie physiographic region across the Chunnenuggee Hills and Southern Red Hills ca. 105 km from the nearest verified specimen (AUM 8963) collected in Coffee Co., Alabama. Because nearby Cowikee Creek is part of the Chattahoochee drainage it might serve as a natural corridor connecting populations to the south.

It should be noted that there were problematic specimens found in the AUM collection. Several specimens (AUM 9443, 9450, 10102) are identified as *P. c. floridana* from Calhoun Co., Alabama, and were examined by RDB on 3 June 2015. They appear to be *P. c. floridana* (lacking distinctive "C" marking on 2nd costal); however, this county is far outside of the known range for the species. This would be approximately 260 km N of the known range and located in the Coosa Valley or Weisner Ridges physiographic provinces. Additional specimens (AUM 9462, AUM 10103) collected by the same collector in the same year and county clearly align with *P. c. concinna* (clearly have the distinctive "C" markings on the 2nd costal). Additionally, specific locality information and the exact collection date are not recorded, making the validity of these specimens suspect. Specimen collected under and Alabama State Department of Conservation and Natural Resources permit (#2014063841468680) issued to RDB.

Thanks to S. Graham for reviewing this note and D. Laurencio and M. Bailey for verifying known localities.

ROGER D. BIRKHEAD, COSAM Outreach, Alabama Science In Motion, Auburn University, Auburn, Alabama 36849-5414, USA (e-mail: birkhrd@auburn.edu); **CHELSEA K. WARD**, Department of Biological Sciences, Auburn University Montgomery, P.O. Box 244023, Montgomery, Alabama 36124-4023, USA.

***PSEUDEMYS SUWANNIENSIS* (Suwannee Cooter).** USA: FLORIDA: Pasco Co.: Pithlachascotee River (28.23648°N, 82.69871°W; WGS 84). 4 June 2015. Timothy J. Walsh and George L. Heinrich. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 175737, photographic voucher). New county record and new river record (Heinrich et al. 2015. J. N. Am. Herpetol. 1:53–59). This record is within an ~79 km distributional gap between the Weeki Wachee and Alafia rivers. The juvenile turtle was basking on a tree branch protruding from the water. Two other *P. suwanniensis* (subadult and adult) were also observed basking on logs within the upper 2.4 km of the Pithlachascotee River, but we were unable to photograph them.

TIMOTHY J. WALSH, Bruce Museum, 1 Museum Drive, Greenwich, Connecticut 06830-7157, USA (e-mail: twalsh@brucemuseum.org); **GEORGE L. HEINRICH**, Heinrich Ecological Services, 1213 Alhambra Way S., St. Petersburg, Florida 33705-4620, USA (e-mail: george@heinrichecologicalservices.com).

***STERNOTHERUS MINOR* (Loggerhead Musk Turtle).** USA: GEORGIA: Putnam Co: Little River/Lake Sinclair near Burtom Rd (33.224444°N, 83.408333°W; WGS 84). 24 June 2014. James F. Mead. Verified by John Jensen. Georgia Museum of Natural History (GMNH 50979, photo voucher). Within expected range, but first county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.). Single adult collected within riprap at the base of seawall along shoreline (elevation 103 m) near the confluence of Little River with Lake Sinclair.

JAMES F. MEAD, **ALFRED J. MEAD**, and **DENNIS PARMLEY**, Department of Biological and Environmental Sciences, Georgia College & State University, Milledgeville, Georgia 31061, USA (e-mail: al.mead@gcsu.edu).

***TERRAPENE CAROLINA* (Eastern Box Turtle)**. USA: GEORGIA: Pickens Co.: Talking Rock, Highway 515 ca. 1.5 km N of junction with Carnes Mill Road. (34.541780°N, 84.517121°W; WGS 84). 29 May 2015. James T. Greenway. Verified by James F. Koukl. Department of Biology, University of Texas at Tyler photo voucher (15-GA-0001). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia, University of Georgia Press, Athens, Georgia. 575 pp.). *Terrapene carolina* is assumed to have a statewide distribution; however, there are no verified records for Pickens Co. Empty shell with evidence of traffic damage found on highway.

***HELODERMA SUSPECTUM* (Gila Monster)**. ARIZONA: Santa Cruz Co.: Atascosa Mountains, ~9.0 km SE Ruby town site (31.413547°N, 111.160586°W; NAD 83), 1373 m elev. Thomas R. Jones and Ross J. Timmons. 18 August 2007. Verified by G. Bradley. University of Arizona (UAZ 57567-PSV, voucher photograph). This is the first Gila Monster documented from the Atascosa and Pajarito mountains complex (Beck 2005. Biology of Gila Monsters and Beaded Lizards. University of California Press, Berkeley, California. 211 pp.). Crossing a road on the south slope of the Atascosas at 1842 h; photographed, collected blood sample, and released.

The nearest vouchered records are in Pima Co. ~52 km NNE in the vicinity of Green Valley and adjacent slopes of the Santa Rita Mountains (many records) and ~51 km NW in the Altar Valley (UAZ 46221). We are aware of no nearby records in Sonora, México (J. C. Rorabaugh, pers. comm.). *Heloderma suspectum* is a species ordinarily found in arid habitats of southeastern Arizona, including semidesert grassland or Sonoran desertscrub, but this site is in more mesic Madrean evergreen woodland (Brown 1994. Biotic Communities: Southwestern United States and Northwestern Mexico. University of Utah Press, Salt Lake City, Utah. 346 pp). That *H. suspectum* has never been found in this area is somewhat surprising given the popularity of these mountains among both amateur and professional herpetologists. However, *Gopherus morafkai* (Sonoran Desert Tortoise) has also recently been documented from the Pajarito Mountains (Babb et al. 2013. Herpetol. Rev. 44:623) suggesting the possibility of relatively recent elevational shifts among some Sonoran Desert species.

G. Bradley provided UAZ data for southeastern Arizona *Heloderma*; additional locality data for Arizona and Sonora were accessed 31 December 2014 through HerpNET2 (http://www.herpnet.org).

THOMAS R. JONES (e-mail: tjones@azgfd.gov) and **ROSS J. TIMMONS** (e-mail: rtimmons@azgfd.gov), Arizona Game and Fish Department, 5000 W. Carefree Hwy., Phoenix, Arizona 85086, USA.

***HELODERMA SUSPECTUM CINCTUM* (Banded Gila Monster).** USA: CALIFORNIA: San Bernardino Co.: Mesquite Mountains (35.43060°N, 115.41260°W; WGS 84). 7 May 2015. Barrett Scurlock. Verified by D. Goodward. Natural History Museum of Los Angeles County (LACM PC1872, photographic voucher). New locality and first record from the Mesquite Mountains, ca. 21 km from nearest known localities in the Kingston Mountains and ca. 24 km at Clark Mountain (Lovich and Beaman 2007. Bull. South. California Acad. Sci. 106:39–58). This record fills a gap in the distribution of *H. s. cinctum* in California. Specimen observed at 1330 h.

***OPHISAURUS ATTENUATUS ATTENUATUS* (Western Slender Glass Lizard).** USA: TEXAS: Jim Hogg Co.: Balluarte Ranch Road (27.18972088°N, 98.58506918°W; WGS 84). 16 May 2015. Mayra Oyervides and (Trey) James D. Petty, III. Verified by Frederic Zaidan, III. University of Texas-Pan American Vertebrate Museum (UTPA 051501, photo voucher). New county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 447 pp.). Extends the currently known distribution 12.45 km E of the Brooks Co. line. On 16 May 2015 at 2019 h one individual was found basking on the north side of Balluarte Ranch Road (a dirt road). This specimen was a subadult and had a partially regenerated tail. Heading east on the same road, we found a second adult specimen at 2033 h and 3.32 km from the first adult. The location is part of the south Texas sand sheet, a unique habitat consisting of mostly sandy soils, with grasslands containing low shrubs, including a number of endemic species of the families Fabaceae, Asteraceae, Hydrophyllaceae, and Malvaceae. This population of *O. a. attenuatus* is presumed to be abundant, but seldom encountered. It is currently listed on the Texas Parks and Wildlife Department's species of greatest conservation need.

MAYRA OYERVIDES, Department of Biology, University of Texas Pan-American, 1201 W. University Drive, Edinburg, Texas 78539, USA (e-mail: mayraoyervides@hotmail.com); **(TREY) JAMES D. PETTY III**, United States Fish and Wildlife Service, Alamo, Texas 78516, USA (e-mail: james_petty@fws.gov).

***PLESTIODON CALLICEPHALUS* (Mountain Skink).** MÉXICO: JALISCO: Municipality of Huejuquilla el Alto : 6 airline km W of Huejuquilla El Alto (22.610586°N, 103.957425°W; WGS 84), 1718 m elev. 19 July 2014. Jorge A. Bañuelos-Alamillo, Rubén A. Carbajal-Márquez, Eric A. Rivas-Mercado, and Marco A. Domínguez-De la Riva. San Diego Natural History Museum (SDSNH HerpPC 5264, photo voucher). First municipality record, with the closest known locality being ca. 159 airline km to the northwest from 3 mi. W of Tepic, Nayarit (Taylor 1935. Univ. Kansas Sci. Bull. 23:19–643). The female lizard and five eggs were found under a rock in a patch of pine-oak forest surrounded by tropical deciduous forest. Municipality of Mezquitic: 15 airline km NNW of Mezquitic (22.518749°N, 103.763393°W; WGS 84), 1919 m elev. 20 July 2014. Rubén A. Carbajal-Márquez, Jorge A. Bañuelos-Alamillo, Eric A. Rivas-Mercado, and Marco A. Domínguez-De la Riva. SDSNH HerpPC 05265, photo voucher. First municipality record, with the closest known locality being ca. 150 airline km NW from Mezquital del Oro, Zacatecas (Taylor 1935, *op. cit.*) The skink was found basking on oak forest ground litter. Both specimens verified by Bradford Hollingsworth.

SQUAMATA — SNAKES

***CEMOPHORA COCCINEA* (Scarletsnake).** USA: ALABAMA: Baldwin Co.: Bon Secour National Wildlife Refuge, AL 180 approximately 14.66 road km W of AL 59 (30.24612°N, 87.83372°W; WGS 84). 24 October 2013. Brian D. Holt. Verified by David Laurencio. Auburn Unviersity Natural History Museum (AUM AHAP-D 968, digital photographic voucher). New county record (Mount 1975. Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University, Alabama. 347 pp.). A single individual observed under pile of scrap lumber in power line right-of-way. The nearest previously published locations in the state occur in Washington Co. to the northwest and Mobile Co. to the west (Mount 1975, *op. cit.*). A query of museum holdings on VertNet (VertNet.org) produced two unpublished records (UF 113794, 113795). Both were collected by Paul E. Moler on 5 June 1979 with no other collection information provided. This record fills a gap in the Gulf Barrier Islands and Coastal Marshes

section of the Southern Coastal Plain ecoregion in southwestern Alabama.

Thanks to Eric Soehren for reviewing this note and David Laurencio for verifying the identification and confirming the county record. Additional online museum records were examined for county occurrences via VertNet.

BRIAN D. HOLT, Alabama Department of Conservation and Natural Resources, State Lands Division, Natural Heritage Section, 64 N Union Street, Suite 464, Montgomery, Alabama 36130, USA; e-mail: brian.holt@dcnr.alabama.gov.

***CEMOPHORA COCCINEA COPEI* (Northern Scarletsnake)**. USA: FLORIDA: Hamilton Co: Suwannee Ridge Mitigation Park Wildlife and Environmental Area (30.44366°N, 83.04613°W; WGS 84). 3 June 2014. Jonathan D. Mays. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 173271, digital photographic voucher). First county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final report, Florida Fish and Wildlife Conservation Commission, Tallahassee, Florida. 524 pp.). Adult male trapped by a drift fence installed in sandhill habitat.

JONATHAN D. MAYS (e-mail: jonathan.mays@myfwc.com), **KEVIN M. ENGE,** and **CODY D. GODWIN,** Florida Fish and Wildlife Conservation Commission, 1105 S.W. Williston Road, Gainesville, Florida 32601, USA.

***COLUBER CONSTRICTOR* (North American Racer)**. USA: TENNESSEE: Morgan Co.: 8.1 km N of Wartburg (36.1777°N, 84.5904°W; WGS 84). 9 August 2008. Ted M. Faust. Verified by Floyd A. Scott. David H. Snyder Museum of Zoology, Austin Peay State University (APSU 19481, color photo). New county record (Scott and Redmond 2008 (latest update: 12 January 2015). Atlas of Reptiles in Tennessee. The Center of Excellence for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at [http://apsu.edu/reptatlas/, accessed 9 March 2015]). A single individual was found crossing Greasy Creek Road at 1410 h on a cloudy day. We have observed, but not photographed, at least two other individuals in this area of Morgan Co. on other occasions.

TED M. FAUST (e-mail: tmfaust21@gmail.com) and **MARTIN K. WOOD**, Clinch River Environmental Studies Organization (CRESO), Clinton, Tennessee 37716, USA (e-mail: woodvflwfs@gmail.com).

***CROTALUS BASILISCUS* (Mexican West Coast Rattlesnake)**. MÉXICO: ZACATECAS: Municipality of Valparaiso: 11 airline km SW of Valparaiso (22.691875°N, 103.634363°W; WGS 84), 1870 m elev. 20 July 2014. Rubén A. Carbajal-Márquez, Jorge A. Bañuelos-Alamillo, Eric A. Rivas-Mercado, and Marco A. Domínguez-De la Riva. Verified by Bradford Hollingsworth. San Diego Natural History Museum (SDSNH HerpPC 5260–5262, photo vouchers). First record for the municipality and only the second for Zacatecas, with the closest known locality being ca. 85 airline km SW from the border between Jalisco and Nayarit (McCranie 1981. Cat. Amer. Amphib. Rept. 283:1–2). The previously known single locality in Zacatecas is ca. 170 airline km SSE from 2.25 km N of Santa Rosa, Moyahua de Estrada, Zacatecas (Ahumada-Carrillo et al. 2011. Herpetol. Rev. 42:397–398). This record also confirms the presence of this species in the Municipality of Valparaiso. Previously, McCranie (1981, *op. cit.*) noted that a badly-damaged DOR specimen found nearby from 18 km NE of Huejuquilla el Alto, Jalisco, could not be assigned with confidence to this species. Our specimen was found DOR in tropical deciduous forest.

***IMANTODES LENTIFERUS* (Blunt-headed Tree Snake)**. BRAZIL: PARÁ: Municipality of Paragominas: mining company Norsk Hydro (3.22944°S, 47.83577°W; WGS 84), 85 m elev. 28 February 2015. Alexandre C. Ascenso and Anderson V. Furtado. Verified by João C. L. Costa. Museu Paraense "Emilio Goeldi," Zoologia, Belém, Pará, Brazil (MPEG 26154). Adult male (SVL 540 mm; TL 217 mm) found in a disturbed lowland area, in a dense ombrophilous forest formation in the area of influence of the mining company Norsk Hydro, near to the ecotonal region between Amazon and Cerrado. This species occurs in the Amazon Basin and Guyana Region of Colombia, Ecuador, Peru, Surinam, French Guiana, Guyana, Bolivia, Venezuela, and Brazil (Myers 1982. Am. Mus. Nov. 2738:1–50; Pérez-Santos and Moreno 1988. Ofidios de Colombia. Museo Regionale di Scienze Naturali, Torino. 520 pp; Donnelly and Myers 1991. Am. Mus. Nov. 3017:1–54; Sampaio and Maciel 2012. Herpetol. Rev. 43:307; Cole et al. 2013. Proc. Biol. Soc. Washington 125:317–578), whereas in Brazilian Amazon, it occurs in the states of Amapá, Amazonas, Rondônia, Pará, and Mato Grosso. First county record, extends known range ca. 170 km SE from the nearest record in Acará municipality, Pará State (Cunha and Nascimento 1993. Mus. Par. Emílio Goeldi Publ. Avuls. 9:1–191), on the right margin of the Amazon River, besides being the southeastern most record from Pará. Specimens were collected under permit number IBAMA 2607/2014 (Instituto Brasileiro do Meio Ambiente e dos Recursos Naturais Renováveis), and this is the publication BRC 0001 of Biodiversity Research Consortium Brazil-Norway (http://brc.museu-goeldi.br/).

New Data on the Distribution of Snakes in Georgia (Caucasus)

The territory of Georgia remains one of the most interesting in the Caucasus for studying the biology of many species of snakes. Despite the publication of a detailed monograph on snakes of the Caucasus (Tuniyev et al. 2009) and subsequent publications (Tarkhnishvili et al. 2002; Frotzler et al. 2011; Tuniyev et al. 2014), a number of aspects of snake biology in the region remain poorly studied. During work in Georgia during 1992, 2009–2014, we obtained new data on the distribution of snake species. We recorded coordinates and elevation of localities using a Garmin GPS navigator; localities are shown in Fig. 1. We highlight several important records here. Specimens are identified by temporary field numbers pending permanent accession to the Institute of Zoology, Georgia collection.

1. We recorded a completely melanistic specimen of *Coronella a. austriaca* Laurenti, 1768 (Figs. 2, 3) on 19 June 2012 in the vicinity of the Roshka village, Dusheti Municipality, Mtskheta-Mtianeti Region (42.5439°N, 44.9139°E; ~1880 m elev.). This is the first significant discovery of melanistic *C. austriaca* in the Caucasus (Doronin 2012), which is extremely rare for this species (Pernetta and Reading 2009).

2. Two melanistic individuals of *Macrovipera lebetina obtusa* (Dwigubsky, 1832) were found on 12 May 1992 at Samshvilde Hill fort, Tetritskaro Municipality, Kvemo Kartli Region (41.5081°N, 44.5022°E; ~760 m elev.). In the Caucasus, a melanistic *M. lebetina* was previously found only in the Eastern Caucasus in Dagestan, Russia (Doronin 2012).

3. We recorded the first population of *Hierophis caspius* (Gmelin, 1789) (Figs. 4, 5) in the east suburb of Rustavi, Kvemo Kartli Region (41.5167°N, 45.0667°E; ~330–410 m elev.) in the valley of the Kura River. At this locality, specimens of different ages were observed in spring and summer during 2009–2014. This locality is significantly isolated from the main range of this species in the Caucasus; previously known localities along the Black Sea coast are approx. 370 km away, while those on the Caspian coast are approx. 290 km distant. We observed this newly recorded population of *H. caspius* to be sympatric with the closely related species *H. schmidti* (Nikolsky, 1909) though at a much lower density than *H. schmidti*; we recorded eight individuals of *H. schimidti* but only two *H. caspius*. This record of *H. caspius* in southeastern Georgia significantly alters knowledge of its distribution in the region (Tuniyev et al. 2009).

4. We recorded several new localities for *Pelias dinniki* (Nikolsky, 1913) (Figs. 6, 7). This includes records from Mtskheta-Mtianeti Region: one adult specimen found on 17 July 2010 at the Sno riverhead, Kazbegi Municipality (42.5983°N, 44.8081°E; ~3000 m elev.) (Fig. 8); one adult specimen found on 07 June 2013 in gorge of Kistinka (= Khde, Brolistskali) Kazbegi Municipality (42.7397°N, 44.6408°E; ~1810 m elev.) (Fig. 9); one adult specimen found on 07 August 2011 in the vicinity of Gudani village (= Gadani), Dusheti Municipality (42.5508°N, 44.9811°E; ~2390 m elev.). These localities are in the territory of Kazbegi National Park and complement the fragmentary data on species range in Georgia. This species is rare in this region. All recorded specimens exhibited bright coloration, with the pattern and color of the body being similar to the *Pelias renardi* complex.

5. Four adult specimens of *Pelias lotievi* (Nilson, Tuniyev, Orlov, Hoggren et Andren, 1995) (Figs. 10, 11) were found on 11 August 2012 in the gorge of Tsovatitskali River in the vicinity of Indurta village, Akhmeta municipality, Kakheti Region (42.4556°N, 45.4381°E; ~2390 m elev.) (Fig. 12). We also found one dead specimen 2 km upriver from that locality (42.4597°N, 45.4281°E;

Baseline Distribution Records for Amphibians and Reptiles in the Upper Peninsula of Michigan

Species distribution maps are useful for a variety of purposes. With the widespread adoption of GIS-based analysis, biogeographic studies utilize distribution data at many scales, including for conservation status assessments. These studies rely upon accurately published distribution data, and standards for publishing new county records are enforced by the Society for the Study of Amphibians and Reptiles (SSAR; Anonymous 2014). These standards require independent verification of voucher specimens. When distribution data are published or otherwise made available (e.g., on a website) without meeting these standards, problems can arise which confuse the record on what is actually known. Here we address distribution data confounded by just such problems for all species of amphibians and reptiles in the fifteen counties comprising the Upper Peninsula of Michigan (U.P.), and reset the record of valid county level distribution status. This is a result of over a decade of field work and a comprehensive review of all distribution data for the U.P., which cannot be added to the scientific record without first establishing a valid baseline.

Holman (2012) provides the most recent published maps for amphibian and reptile distribution in Michigan. For the past fifteen years we have performed herpetofaunal inventories and monitoring in the U.P. for a variety of initiatives, systematically collecting all known occurrence records, examining voucher material, and constructing an occurrence database with vetting ranks. Recently we noted many discrepancies between Holman's published maps and our collected data. We suspected that many of these resulted from an aborted review of records, given that the author passed away before completing the manuscript. Here we present corrections and updates to the distributions of U.P. herpetofauna. Since many of the corrections suppress previously published county records, we hope that future confusion resulting from repeated citation of erroneous or undocumented records might be avoided by treating this review as a new baseline to which future updates can be added. We hope this reassessment adds value to the substantial contributions of the many past and present Michigan herpetologists whose work we reviewed, and provides a newly vetted opportunity to build upon this valuable knowledge base.

Knowledge of Michigan herpetofaunal distribution has advanced through several stages from Ruthven et al. (1928) through Johnson (1965), Tinkle et al. (1979), Harding (1997), Harding and Holman (1990, 1999), Holman (2004), Holman and Harding (2006), and Holman (2012). Most of these publications have used "blob" maps—polygons drawn to approximate the suspected ranges of species. Blob maps represent a hypothesis on the extent of a species' range, based on the author's review of known records and assumptions about undocumented range limits. Blob maps usually do not provide fine precision on distributions, but are meant as coarse representations of the area within which a species might be found if suitable habitat is present, and authors may warn against using them as a basis for new county distribution records (see Harding 1997).

Blob maps contrast with dot maps which plot a point at each known species occurrence, sometimes generalizing these dots to township or county centers. Traditionally, dot maps have been based on empirical data (e.g., specimen vouchers), and behind each dot on a published map would be a list of specimens examined, or at least a list of the institutions wherein these vouchers reside (see Pfingsten et al. 2013). In some instances, non-vouchered records (i.e., observations) are used in dot maps, typically differentiated from voucher-based dots by using open circles, rather than solid dots (see Ruthven et al. 1928; Vogt 1981).

Converting blobs to dots for range maps is not recommended. Dots derived from blobs can easily be misconstrued as being confirmed records, or as having a finer precision than they actually do. This generates confusion and can result in compounded errors when cited. To minimize such misinterpretation, dot symbols should differentiate between vouchered and unvouchered records (as only vouchered records can be independently verified) and sources should be cited in text or appendices. We also recommend differentiating between verified and unverified voucher material, as errors do persist in museum specimen data, and these can only be discovered by examining material. In short, citing sources and specimens examined enables future workers to avoid having to repeat the work.

Distribution record standards are set by the SSAR (Anonymous 2014). To be accepted by the scientific community, records generally must meet two criteria—physical evidence (e.g., a voucher specimen or photograph), and independent verification. Specimen vouchers should be deposited in a university or museum collection with complete locality and other data, and catalog numbers provided. This is necessary so that specimens are properly curated in an accredited permanent collection. Photo vouchers have substantially less longevity than specimen vouchers, even when properly curated (Rothenberg 1995), and provide substantially less scientific information as well (Graeter et al. 2013). Moreover, care must be taken to ensure that the photos are of sufficient quality and that they show enough diagnostic characters to confirm a species' identification (Graeter et al. 2013). Hence, photos should only be used when voucher specimens cannot be collected. Private collections and web-based photo services are not considered an acceptable permanent record (Anonymous 2014). Often these exist at the discretion of a single individual, and can easily be lost or discarded during major life events, such as a relocation, upon death, or computer failure (for digital collections). When such programs collect significant records, these vouchers should be deposited at an accredited museum for acceptance into the scientific record,

enabling them to be queried through search engines and direct correspondence with institutions.

The second requirement for county record acceptance, independent verification, is a basic tenant of science. The scientific method rejects non-evidence based claims, requiring evidence that can be independently corroborated. For species distributions to be so verified physical evidence must exist, typically properly preserved voucher specimens, photos, audio recordings, or tissue samples. Observational records cannot be corroborated in this manner, but do have value in filling distribution gaps in the verified record, in natural history studies, and in biogeographical analyses. They should not be used as evidence for range extensions.

We were at first perplexed at how many county records for the U.P. in Harding (1997) and in Holman (2012) did not match with our review of historical occurrence data. Moreover, our extensive field surveys failed to discover many species in the indicated counties. Holman's (2012) maps indicate whether or not he had evidence for species occurrence in a county, with dots generalized to one per county (approximately the center), although some major islands were treated separately. These dots are not ranked with differing symbols to indicate date of most recent occurrence, or for voucher status, as in Phillips et al. (1999). However, Holman does provide more detail on sources in some species accounts. In early 2014 James Harding discovered and shared with us a set of working maps that were the basis for Holman's published maps, and were among Holman's notes preserved in the Michigan State University Museum. These working maps included notes indicating the source used for each county record. We compared these working maps to our comprehensive database and unpublished field notes, and quickly discovered a major discrepancy. In sum, Holman had used blob maps as evidence of occurrence, along with personal observations and those of colleagues, and observations from state agency programs, converting all of these sources to undifferentiated county dots. In particular, Casper (2002) was cited often. However, Michigan maps in Casper (2002) were county-level shading derived from digitized maps from the web site of the Herpetology Collection at the University of Michigan Museum of Zoology (representing UMMZ specimens) and Harding's (1997) blob maps. Harding had a policy of making conservative blob maps, extending somewhat beyond confirmed records, given his experience that more records are usually acquired when these areas are surveyed (J. Harding, pers. comm.). While these caveats on Michigan data sources are discoverable through the appendices included with Casper (2002), and Harding's (1997) introduction, they may not be otherwise apparent. Many of the discrepancies between Holman's 2012 maps and our data can be traced to an incorrect assumption that Casper's 2002 maps, derived in turn from Harding (1997), were voucher based. We correct these assumptions here.

The literature that has cited voucher material for Michigan amphibian and reptile distribution is limited (e.g., Ruthven et al. 1928). We examine this history and newly apply the aforementioned standards for documentation to these and all other distribution data sources. We provide a new vetted baseline upon which new county records can be added, with assurance that scientific standards are applied. We discuss county records without proper documentation in the species accounts, and encourage the collection of voucher specimens for deposit at accredited institutions. Where collecting a voucher specimen is a conservation concern, photo vouchers can serve this purpose if they clearly show enough diagnostic characters for a firm identification to be made (for Michigan species see Graeter et al. 2013), and are properly deposited as detailed above.

We have undoubtedly missed some voucher material despite our best efforts to be comprehensive, and we welcome additions. We do note some instances where vouchers are known to exist (mostly photos) but have not been submitted to acceptable repositories. Properly documenting these findings is encouraged. The collection and deposit of voucher material into acceptable repositories should be standard practice for important records gained through research, or collected through public programs such as the Michigan Frog and Toad Survey (MFTS) and the Michigan Herp Atlas (MHA). We caution against citing works that are non-voucher based when publishing new county records. For example, Wogahn and Ray (2014) published a new county record for Wisconsin citing a non-voucher based blob map (Christoffel et al. 2002) as support for the record being new, rather than using available voucher-based references for Wisconsin (e.g., Vogt 1981, Casper 1996, and subsequent geographic distribution accounts in *Herpetological Review*). The practice of citing non-vouchered sources to support new records may result in errors. We therefore make an appeal to return to voucher-based standards in order to advance science in a reputable manner. Programs and websites that gather occurrence data can partner with an institution who will accept voucher material for documenting noteworthy records.

Methods

Using our vetted database, Holman's unpublished notes, the published literature, and all other available data sources, we reviewed the empirical evidence for the occurrence of each species in each U.P. county for adherence to SSAR standards (Anonymous 2014). We reviewed records from museum collections, the MFTS, MHA, Michigan Natural Features Inventory (MNFI), Herpetological Education and Research Project (H.E.R.P. 2014), and HerpMapper (2014). We used Holman (2012) and Ruthven et al. (1928) as a basis for assigning the newly vetted records to one of three ranks. Voucher material supporting observational records in Ruthven et al. (1928) was treated as re-confirming these records, rather than as new county records, as these have been generally accepted as valid records for many decades, and we did not view them as new. Instead, we now support these with empirical evidence meeting modern standards.

We do not assume evidence is available to support published blob maps that are derived works and/or do not cite source data (e.g., Harding 1997; Harding and Holman 1990, 1999; Casper 2002, Holman 2012, Tekiela 2014). As Harding (1997) notes, typically these are not intended to be used as a basis for new distribution records.

All non-vouchered records were considered observational. Photo "vouchers" posted only to a website are problematic (e.g., some MHA, H.E.R.P., and HerpMapper records). These do not meet SSAR standards for a county record as they are not deposited in a curated collection where all associated data can be examined. Moreover, since some of the photos are copyrighted (MHA), only the copyright holder can deposit them as required. All such records with photo documentation are therefore treated as observational here, pending deposition into museum collections meeting SSAR standards. Properly depositing photos with full data into museum collections is fairly easy, and HerpMapper will currently accommodate this data transfer on request.

The three ranks we applied to records are as follows:

1) Accepted: County records for which we could find properly deposited specimen or photo vouchers corroborating a prior published record. We cited the earliest voucher we could find, along with the earliest voucher we verified, if any (Tables 1–4).

2) Suppressed: These are published records for which we could find no supporting vouchers meeting the SSAR standard. These were mostly from published blob maps, but we corrected some errors as well. These counties may have observational records for the suppressed species (e.g., author notes, MHA or MFTS records), which are discussed, as observational records suggest that the species does in fact occur and vouchers can be collected with relative ease to properly document occurrence.

3) New: These are vouchers we collected for counties that previously had no supporting voucher material meeting SSAR standards, and had not been previously published by Ruthven et al. (1928). Records from Holman's 2012 maps that are supported only (to our current knowledge) by our collections were considered new, as neither his notes nor our correspondence with him prior to his passing indicated that he utilized any of our voucher material.

Below we review each species for specimen vouchers supporting occurrence in each county (Tables 1–4). We discuss the empirical evidence for changing county statuses, and list accepted, suppressed, and new county records. Specimen vouchers examined are cited, and photo vouchers are only mentioned if specimen vouchers were not found. Sources and acronyms for voucher material follow Sabaj Pérez (2014). For space considerations, we have not supplied new maps, but rather present tabular data for easy reference. We include notes on Isle Royale because of its size and distance from the mainland, but do not address species occurrence on other islands. The number of decimal places in coordinates reflects precision estimates. Common and scientific names follow Crother et al. (2012). All GPS locations are WGS 84.

CAUDATA — SALAMANDERS

***AMBYSTOMA LATERALE* AND POLYPLOIDS (Blue-spotted Salamander complex).** Dickinson Co.: Benton Lake Road south of Benton Lake (45.8735°N, 87.9029°W). 1 October 2014. Ryne D. Rutherford. UMMZ 243460. Verified by Gregory Schneider. New county record. Under log along edge of ephemeral pond. Menominee Co.: along Vega Road 01 ca. 2.08 km S of Sand Road (45.8174°N, 87.61454°W). 1 October 2014. Ryne D. Rutherford. UMMZ 243459. Verified by Gregory Schneider. New county record. Under log along road.

The most common salamander in the U.P., verified from all counties (with Dickinson and Menominee first county records provided here) and Isle Royale (Casper 2008). A Dickinson Co. photo from 2011 is also posted on the MHA website without full data. Holman (2012) included an account for polyploid hybrids of *A. laterale* and *A. jeffersonianum*, but we do not attempt to segregate out polyploid records here, as a taxonomy for these combinations has yet to be settled (Bi and Bogart 2010). It is possible that there are instances of polyploid populations in some U.P. counties, and this should be investigated.

Accepted: All counties.

Suppressed: None.

***AMBYSTOMA MACULATUM* (Spotted Salamander).** Baraga Co.: Ottawa National Forest, along FR 2200 ca. 0.6 km N of Hwy 227 (46.546412°N, 88.666084°W). 4 June 2013. Ryne D. and Jenny L. Rutherford. UMMZ 1250 (photo). Verified by Gregory Schneider. New county record. Photo of egg mass in ephemeral pond. Chippewa Co.: South end of beaver pond ca. 0.8 km S of Cranberry Lake (45.968800°N, 84.016529°W). 15 September 2014. Ryne D. Rutherford. UMMZ 243462. Verified by Gregory Schneider. New county record. Under old log in open grassy area along open lake shoreline. Delta Co.: Gravel pit off Limpert Road ca. 2.4 km NW of Hwy 35 (45.572621°N, 87.286464°W). 27 August 2014. Jenny L., Cypress, and Ryne D. Rutherford. UMMZ 243461. Verified by Gregory Schneider. New county record. Under wet board in sandy gravel pit. Houghton Co. Ottawa National Forest, forest road ca. 0.68 km NE of Dunn Lake (46.422558°N, 88.835821°W). 21 July 2010. Gary S. Casper, Thomas G. Anton, Dave Mauger. FMNH 281085. Verified by Alan Resetar. New county record. Under log in old quarry next to spruce bog. Keweenaw Co.: Along Mandan Rd. ca. 1.6 km N of Maniton Lookout Rd. (47.4457°N, 87.7692°W; WGS 84). 20 May 2011. Ryne D. and Jenny L. Rutherford. Verified by Gregory Schneider. New county record. UMMZ 1232 (photo). Photo of ca. 87 egg masses. Luce Co.: Along Camp 9 Rd. near Lost Lake, wetland on E side of road (46.4583°N, 85.7986°W; WGS 84). 10 May 2011. Ryne D. and Jenny L. Rutherford. Verified by Gregory Schneider. New county record. UMMZ 1231 (photo). Photo of ca. 22 egg masses. Menominee Co.: Small gravel pit on N side of Hayward Lake Rd. (45.3473°N, 87.5132°W; WGS 84). 4 August 2008. Ryne D. Rutherford. Verified by Gregory Schneider. New county record. UMMZ 1248 (photo). Photo of adult under log.

A common but cryptic salamander throughout the U.P., now confirmed from all counties except Dickinson (we have an observational record but lack a voucher). Spotted Salamanders have been confirmed in Thunder Bay, Ontario (ROM 1011–13, 1016, 11981), but are not known from Isle Royale (Casper 2008).

Accepted: All counties except Dickinson.

Suppressed: Dickinson (observation only).

***AMBYSTOMA TIGRINUM* (Eastern Tiger Salamander):** Three larval specimens were collected in 1962 and 1963 from Merwin Lake in Alger Co. (Hensley 1964). These were reportedly deposited at the Department of Zoology, Michigan State University, but only one specimen could be located (MSUM 10935). Hensley (1964) dissected one larval specimen and found well-developed eggs in both ovaries, indicating neoteny. MSUM 10935 is a recently transformed adult, which presumably metamorphosed in Hensley's lab. No other records are available and aquatic funnel trap surveys conducted at the site in 2008 (RDR, unpubl. data) yielded negative results. We suspect the population was introduced with bait minnows and is now extirpated, as the species is otherwise unknown from the U.P. Holman (2012) suggested they may be a glacial relict population, but there is no other evidence of the species' range ever having extended this far north post-Pleistocene. We consider this occurrence an anomaly, which should be treated as accidental or introduced on range maps, typically symbolized by an X or question mark.

Accepted: None.

Suppressed: Alger (possibly introduced).

New: None.

***HEMIDACTYLIUM SCUTATUM* (Four-toed Salamander).** Baraga Co.: Ottawa National Forest, McCormick Wilderness, Evergreen Lake (46.7115°N, 88.0381°W). 20 April 2012. Ryne D. and Jenny L. Rutherford. UMMZ 243173. Verified by Gregory Schneider. On nest with eggs in sphagnum moss. Delta Co.: Ca. 0.34 km SW of junction of CR511 and K10 Road (45.7871°N, 86.8674°W).

12 May 2014. Ryne D. Rutherford. UMMZ 243464. Verified by Gregory Schneider. New county record. Adult on nest with eggs, ephemeral pond in red oak/mixed hardwood forest with scattered mossy logs. Houghton Co. Ottawa National Forest, wetland along Forest Road 1360 (46.6384°N, 88.8091°W). 11 June 2003. Gary S. Casper. MPM 33290. Verified by Gregory Schneider. New county record. Roadside wetland of alder in mixed northern hardwood. Mackinac Co. ca. 1.2 km N of Big Knob Campground on Big Knob Road (46.0479°N, 85.5861°W). 21 September 2014. Jenny L., Cypress and Ryne D. Rutherford. UMMZ 243463. Verified by Gregory Schneider. New county record. Under birch log. Menominee Co. Along River Road ca. 2.4 km N of jct. with Santosa Lane (45.4489°N, 87.8342°W). 10 May 2014. Ryne D. Rutherford. UMMZ 1241 (photo). Verified by Gregory Schneider. New county record. In mossy clump in ephemeral pond along road. Ontonagon Co. Ottawa National Forest, west side of Choate Road just south of Steusser Lake (46.4432°N, 89.2507°W). 10 June 2003. Gary S. Casper. MPM 33291. Verified by Jeffrey A. Soltesz. New county record. On nest with Speckled Alder, sedges, and sphagnum moss.

Currently verified from most U.P. counties, but surveys are incomplete and require special knowledge for success. Probably occurs in all counties, but vouchered records are still lacking for four, with Holman's notes indicating these dots were inferred from Casper (2002). Holman's Schoolcraft Co. dot is attributed to a note from J. Harding. They appear to be absent from Isle Royale (Casper 2008).

Accepted: Alger, Baraga, Chippewa, Delta, Gogebic, Houghton, Iron, Mackinac, Marquette, Menominee, Ontonagon counties.

Suppressed: Schoolcraft (observational record). Dickinson, Keweenaw, Luce (no records) counties.

***NECTURUS MACULOSUS MACULOSUS* (Common Mudpuppy).** Probably found throughout the U.P., but vouchers lacking for Iron, Marquette, and Ontonagon counties. Known to occupy harbors and shoals of lakes Superior and Michigan, and inland streams and lakes, especially where streams are (or were) connected to the Great Lakes. Holman's notes indicate Iron and Ontonagon county dots were inferred from Casper (2002), and the source for Marquette Co. is unattributed. Ruthven et al. (1928) included an open circle for Iron Co., indicating a non-vouchered record, but we have been unable to discover any other records for this county. Mudpuppies are verified from Isle Royale (Casper 2008), but may have declined or become extirpated there and elsewhere, especially where lampricide treatment is practiced (Matson 1990, 2005).

Accepted: All counties except Iron, Marquette and Ontonagon counties.

Suppressed: Iron, Marquette, Ontonagon (no records) counties.

New: None.

***NOTOPHTHALMUS VIRIDESCENS* (Eastern Newt).** Gogebic Co.: ca. 1.3 km E of South Boundary Road along dirt road (46.697872°N, 89.950110°W). 17 July 2014. Ryne D. Rutherford. UMMZ 243465. Verified by Gregory Schneider. New county record. Eft found under log.

Found throughout the U.P., but vouchers are currently lacking for Dickinson Co. and there appear to be gaps in the range (unpubl. data). Holman's notes indicate the Dickinson Co. dot was inferred from Casper (2002). This species is verified from Isle Royale (Casper 2008).

Accepted: All counties except Dickinson.

Suppressed: Dickinson (no records) Co.

***PLETHODON CINEREUS* (Eastern Red-backed Salamander).** This common salamander is verified from every county in the U.P. They appear to be absent from Isle Royale (Casper 2008).

Voucher Specimens: All counties.

Suppressed: None.

New: None.

ANURA — FROGS

***ANAXYRUS AMERICANUS AMERICANUS* (Eastern American Toad).** One of the most widespread and abundant species in the U.P., it is accepted from all counties and Isle Royale (Casper 2008).

Accepted: All counties.

Suppressed: None.

New: None.

***HYLA CHRYSOSCELIS* (Cope's Gray Treefrog).** A rare frog in the U.P. often misreported based on calls being confused with *Hyla versicolor*. Reported from Baraga Co. by the Keweenaw Bay Indian Community Frog and Toad Survey, and from Mackinac Co. by the MFTS, these records are considered observational pending supporting voucher specimens with karyotype or sonogram evidence. Also reported from Schoolcraft Co. by the Seney National Wildlife Refuge (Anderson 1982), but vouchers (MSUM 8271–72, UMMZ 166599) lack supporting evidence to distinguish them from *H. versicolor* (although J. Harding states recordings are available). However, we (RDR) have confirmed presence at Seney NWR and have a video of a calling frog there, so we accept this county record. Holman's notes indicate that dots for all counties except Houghton were inferred from Casper (2002). The Houghton Co. record is based on MFTS data (Sargent 2012), with a supporting note stating calls were confirmed by tape recording or local expert (Sargent 2000). We treat this as an observational record. At this time we consider this species occurrence in the U.P. limited to the Seney NWR, and encourage the deposition of additional voucher material with digital audio recordings of the specimen calling with temperature data. The habitat where this species is found at Seney NWR is unusual for the U.P. (large sedge meadows).

Accepted: Schoolcraft Co.

Suppressed: Alger, Baraga, Chippewa, Delta, Dickinson, Gogebic, Houghton, Iron, Keweenaw, Luce, Mackinac, Marquette, Menominee, and Ontonagon counties.

New: None.

***HYLA VERSICOLOR* (Gray Treefrog)** Baraga Co.: T49N, R34W, Section 16 (section centroid 46.6441°N, 88.5646°W). 28 June 1967. Richard E. Fitzner. MSUM 10096. Verified by James Harding. New county record. Delta Co.: near 6463 East Stonington AA.5 Road (45.7793°N, 86.8260°W). 30 June 2012. Ryne D. Rutherford. UMMZ 243457. Verified by Gregory Schneider. New county record. Calling on Ironwood (*Ostyra virginiana*) branch in forest. Houghton Co.: (reconfirmed), on FR-16 (46.5229°N, 88.8875°W). 2 June 2014. Gary S. Casper, Julia L. Robson. UMMZ 243451. Verified by Gregory Schneider. New county record. Iron Co. (reconfirmed): Mint Pond, N side of W Brule Lake Rd., Ottawa National Forest (46.0712°N, 88.7984°W; WGS 84). 21 July 2014. Ryne D. Rutherford. Verified by Gregory Schneider. UMMZ 243473. New

county record. Ontonagon Co.: Ottawa National Forest, Jack Pine Lake (46.5617°N, 89.0246°W). 19 July 2010. Ryne D. and Jenny L. Rutherford. FMNH 281081. Verified by Alan Resetar. New county record.

One of the most widespread and abundant species in the U.P., found in all counties. For this study, we assumed all *Hyla* voucher specimens were *H. versicolor* unless otherwise indicated by collecting notes, karyotype, or sonogram evidence. The Schoolcraft Co. specimens collected at Seney National Wildlife Refuge (MSUM 8271–72, UMMZ 166599) however, could be *H. chrysoscelis* (see above). Luce Co. lacks voucher specimens. For Chippewa Co., tadpole specimens (UMMZ 228023) were too desiccated to confirm, and MSUM 8273 cataloged as *Hyla* sp. was determined to be *Pseudacris crucifer*. Both Chippewa and Luce counties have observational records (GSC, unpubl. Data; MFTS), and we are confident this species can be confirmed with proper vouchers (e.g., Luce Co. MHA photo record 3192 could be submitted as documentation). Holman's notes do not attribute sources for Chippewa or Luce counties, and cite the MFTS for the Baraga Co. record. We provide the first published Baraga Co. voucher here (specimen re-determined from an original identification of *Pseudacris nigrita*). Houghton and Iron county observational records were provided by Ruthven et al. (1928), and we here reconfirm these counties with first published vouchers, along with new Delta and Ontonagon county records. Rare on Isle Royale, but a recent 2012 sighting (P. Brown, pers. comm.; MHA record 2613).

Accepted: All counties except Chippewa and Luce.

Suppressed: Chippewa (observations), Luce (observations and MHA photo) counties.

***PSEUDACRIS CRUCIFER* (Spring Peeper).** Verified from every U.P. county except Luce. Luce Co. has observational records from the MFTS and our surveys, but vouchers are lacking. For Holman's Luce Co. dot, MFTS data (Sargent 2012) is cited as the source. Johnson (1965) states this species is recorded from all U.P. counties, but there is no indication he examined any material from Luce Co. Verified from Isle Royale (Casper 2008).

Accepted: All counties except Luce.

Suppressed: Luce Co.

New: None.

***PSEUDACRIS MACULATA* AND *P. TRISERIATA* (Chorus Frogs).** Gogebic Co.: Ottawa National Forest along FR 8100 (46.3716°N, 89.7845°W). 4 May 2012. Gary S. Casper, David Mauger, Ryne D. and Jenny L. Rutherford. UMMZ 242996. Verified by Gregory Schneider. New county record. In forested ephemeral pond, many observed and calling from pond over several days.

The recent reorganization of chorus frogs based on mtDNA analysis (Moriarty Lemmon et al. 2007) suggests that all U.P. occurrences are *P. maculata*. However, no samples from the U.P. were evaluated. There is no solid evidence (yet) for chorus frogs in the eastern and central U.P., but if eastern specimens are later obtained they are more likely to be *P. triseriata*. We suspect that *P. maculata* is colonizing from Wisconsin in the west. We treat these as a species complex here, pending further molecular studies to resolve this issue. The U.P. is at a range limit, where these species may cycle through range expansions and retractions over time, resulting in ephemeral populations and rarity.

Published chorus frog distribution is currently more confused than any other U.P. amphibian. Ruthven et al. (1928) listed only unvouchered records from Iron and Dickinson counties. Since then, unverified records have been published for nearly all other counties (Holman 2012; Tekeila 2014), but only three counties have actual voucher material, and one of those (Gogebic) is newly published here. Interestingly, the Tekiela (2014) range map is almost the exact opposite of the actual U.P. distribution, whereas Harding's (1997) blob map closely reflects actual data. In our experience, the trill calls of the Spring Peeper are often mistaken for Chorus Frog calls (as are *A. americanus* calls on occasion), and this probably results in many erroneous reports to volunteer frog call survey programs. Calls should be confirmed by collecting voucher specimens or photos.

Chorus frog records from frog call survey programs are available for Baraga, Houghton, Mackinac, and Marquette counties, but are suspect without supporting documentation. We have not heard chorus frogs in these counties in any of our surveys. In Holman's notes, Alger, Chippewa, Delta, Dickinson, Houghton, mainland Keweenaw, Luce, Mackinaw, Marquette, Menominee, and Schoolcraft county records are attributed to MFTS data (Sargent 2012), and are here suppressed. Holman's notes do not attribute the Baraga Co. dot to any specific source, but we redetermined a 1967 specimen labeled as "*Pseudacris nigrita*" as *Hyla versicolor* (MSUM 10096). *P. maculata* is verified from Isle Royale (Casper 2008).

Accepted: Gogebic, Iron, Keweenaw (Isle Royale only) counties.

Suppressed: Alger, Baraga, Chippewa, Delta, Dickinson, Houghton, Luce, Mackinac, Marquette, Menominee, and Schoolcraft (observational only) counties.

***LITHOBATES CATESBEIANUS* (American Bullfrog).** Dickinson Co.: Little Fumee Lake (45.8206°N, 87.9537°W). 20 May 2011. Ryne D. and Jenny L. Rutherford. UMMZ 1242 (photo). Verified by Gregory Schneider. New county record. In cattails along a lake edge.

American Bullfrogs have a patchy distribution in the U.P., possibly as a result of one or more anthropogenic introductions (e.g., tadpoles mixed with bait minnows). Johnson (1965) quotes David Johnson, a Michigan Conservation Officer, regarding introductions in Marquette Co. by individuals attempting to raise them commercially. Populations could also be naturally invading from Wisconsin and some may be post-glacial relics (Holman 2004). Holman's notes indicate that dots for Alger, Chippewa, Delta, Houghton, Iron, Keweenaw, and Ontonagon counties were inferred from Casper (2002); while dots for Dickinson and Menominee counties are attributed to MFTS data (Sargent 2012). American Bullfrogs are absent from Isle Royale (Casper 2008).

Accepted: Baraga, Dickinson, Gogebic, Luce, Mackinac, Marquette, and Schoolcraft counties.

Suppressed: Alger, Houghton (observations only). Chippewa, Delta, Iron, Keweenaw, Menominee, and Ontonagon counties (no records).

***LITHOBATES CLAMITANS* (Green Frog).** A very widespread and abundant species in the U.P., verified from all counties and from Isle Royale (Casper 2008).

Accepted: All counties.

Suppressed: None.

New: None.

***LITHOBATES PALUSTRIS* (Pickerel Frog).** Rare and local in the U.P., absent from Isle Royale (Casper 2008). Easily confused with *L. pipiens*, Baraga Co. observations from the Keweenaw Bay

Indian Community Frog and Toad Survey, and Luce County observations from the MFTS, are suppressed without supporting documentation, as are Houghton Co. observations provided in 2010 by the MHA. Holman's notes indicate that dots for Alger, Chippewa, Delta, Dickinson, Gogebic, Houghton, Keweenaw, Luce, Mackinac, and Schoolcraft counties were inferred from Casper (2002), and Iron Co. is attributed to MFTS data (Sargent 2012), now suppressed without supporting documentation. Johnson (1965) states this species is recorded from Chippewa Co., but we are unable to find any evidence for this. We have never encountered this species in the U.P. despite extensive fieldwork. It is very rare with the last confirmed record in 1947. Any additional encounters should be documented and published.

Accepted: Marquette, Menominee.

Suppressed: Baraga, Luce (observations only). Alger, Chippewa, Delta, Dickinson, Gogebic, Houghton, Iron, Keweenaw, Mackinac, Ontonagon, Schoolcraft (no records) counties.

New: None.

***LITHOBATES PIPIENS* (Northern Leopard Frog)**: A common species verified in every county, but absent from Isle Royale (Casper 2008). Anecdotal evidence suggests that the species has declined dramatically in the U.P. and large range gaps exist (our unpublished data), although it is still extant in every county.

Accepted: All counties.

Suppressed: None.

New: None.

***LITHOBATES SEPTENTRIONALIS* (Mink Frog)**: Found throughout the U.P. with verified specimens from all counties except Luce. Four Luce Co. observations reported by the MHA are undocumented. Holman's notes for his Luce Co. dot are not attributed to any specific sources. Johnson (1965) states this species is recorded from all U.P. counties, but there is no indication he examined any material from Luce Co. This species is verified from Isle Royale (Casper 2008).

Voucher Specimens: All counties except Luce.

Suppressed: Luce Co.

New: None.

***LITHOBATES SYLVATICUS* (Wood Frog)**: An abundant frog verified in every U.P. county and from Isle Royale (Casper 2008).

Voucher Specimens: All counties.

Suppressed: None.

New: None.

TESTUDINES — TURTLES

***CHELYDRA SERPENTINA* (Snapping Turtle)**. Alger Co.: (reconfirmation) Pictured Rocks National Lakeshore, Sand Point (46.4494°N, 86.6034°W). 5 June 2004. Gary S. Casper, Thomas G. Anton, David Mauger. UMMZ 1236–7 (photo). Verified by Gregory Schneider. New county record. Two caught in turtle trap. Houghton Co.: (reconfirmation) Ottawa National Forest, stream crossing (unnamed tributary of Beaver Creek) at FR 1250 (46.5498°N, 88.9164°W). 6 June 2012. Ryne D. and Jenny L. Rutherford . UMMZ 1239 (photo). Verified by Gregory Schneider. New county record. Digging on roadside. Iron Co.: (reconfirmation) Ottawa National Forest, Jumbo River at FR 4080 (46.4147°N, 88.9708°W). 18 June 2013. Ryne D. and Jenny L. Rutherford. UMMZ 1255 (photo). Verified by Gregory Schneider. New county record. Photo of depredated nest. Keweenaw Co.: Across from Bette Gris Preserve parking lot along Gay Lac La Belle Road (47.3586°N, 87.9611°W). 19 May 2011. Stefanie M. Nadeau, Gary S. Casper. UMMZ 1233 (photo). Verified by Gregory Schneider. New county record. In swale wetland. Luce Co.: Along Camp 9 Road near Lost Lake (46.45831°N, 85.7986°W). 10 May 2011. Ryne D. and Jenny L. Rutherford . UMMZ 1234 (photo). Verified by Gregory Schneider. New county record. Ontonagon Co.: Ottawa National Forest, Steusser Lake (46.4512°N, 89.2485°W). 7 June 2010. Gary S. Casper. FMNH 281365. Verified by Alan Resetar. New county record. Juvenile found along shoreline.

Found throughout the U.P. but vouchers lacking for Baraga Co. The only Alger Co. specimen voucher was lost in the CMU collections fire, but we here provide a new reconfirming photo voucher. Holman's notes indicate that the Baraga Co. dot was inferred from Casper (2002), but Robinson and Werner (1975) also published an observational record and a 2014 photo on the MHA site could be submitted as a voucher. Snapping Turtles were noted as present in Houghton and Iron counties by Ruthven et al. (1928) and Johnson (1965) but without vouchers, and we reconfirm these by providing new photo vouchers (Table 3). Iron and Keweenaw county photos from 2011 are also posted on HerpMapper (HM 9038, 9058) and duplicated on H.E.R.P. and MHA websites. Snapping Turtles are not known from Isle Royale (Casper 2008).

Accepted: Alger, Chippewa, Delta, Dickinson, Gogebic, Houghton, Iron, Keweenaw, Luce, Mackinac, Marquette, Menominee, Ontonagon, and Schoolcraft counties.

Suppressed: Baraga Co. (literature and MHA photo records)

***CHRYSEMYS PICTA* (Painted Turtle)**. Alger Co: (reconfirmed). Pictured Rocks National Lakeshore, wetland along Hwy 58 (46.4911°N, 86.3846°W,). 3 June 2004. Gary S. Casper. MPM 33483. Verified by Alan Resetar. New county record. Juvenile in turtle trap. Baraga Co: Little Lake (46.6471°N, 88.5599°W,). 16 May 2014. Gary S. Casper, Ryne D. Rutherford. UMMZ 243471. Verified by Gregory Schneider. New county record. Small lake in Jack Pine managed forest, turtle found dead along shore, probably winter kill. Iron Co.: (reconfirmed) Ottawa National Forest, jct W Brule Lake Rd and Hagerman Lake Rd (46.0714°N, 88.7941°W). 10 June 2010. Gary S. Casper. FMNH 275484. Verified by Alan Resetar. New county record. Hand-captured juvenile crossing road. Mackinac Co.: Along unnamed road ca. 0.4 km S of Hwy 134. (46.0110°N, 84.5185°W). 18 September 2014. Ryne D. Rutherford. UMMZ 1245–6 (photos). Verified by Gregory Schneider. New county record. Swimming near edge of large quarry pond.

Found throughout the U.P. with vouchers confirmed for every county, with Baraga and Mackinac vouchers newly presented here. Ruthven et al. (1928) included a solid dot representing a specimen for Alger Co., which we could not locate, but it may have been UMMZ 51953, a specimen without any data other than county. We reconfirm this record here with a new voucher collected in 2004. Likewise, Ruthven et al. (1928) provided a hollow dot for Iron Co. which we reconfirm with a new voucher collected in 2010 (Table 3). Baraga and Mackinac county photos from 2010 are also posted on HerpMapper (HM 8736, 8785) and duplicated on H.E.R.P. Several Baraga and one Mackinac Co. photo are also posted on the MHA site but lack full data. This species is verified from Isle Royale (Casper 2008).

Accepted: All counties.

Suppressed: None.

***EMYDOIDEA BLANDINGII* (Blanding's Turtle).** Dickinson Co.: On Swanson Rd, 1 mile in from M95 (45.9372°N, 88.0490°W). 18 July 2011. Bill Baily. UMMZ 1240 (photo). Verified by Gregory Schneider. New county record. Menominee Co.: On north side of Snakey Lake Rd (45.3567°N, 87.7989°W). 2 May 2007. Ryne D. and Jenny L. Rutherford. UMMZ 1247 (photo). Verified by Gregory Schneider. New county record. Basking on log in ephemeral pond.

This species is rare and at its range limit in the U.P., with an isolated population in Marquette Co., and new Dickinson and Menominee county records provided here. Our Dickinson Co. photo voucher confirms a skeleton collected by Johnson (1965), which specimen we could not locate. Chippewa (MNFI 2002), Iron (MNFI 2003), Schoolcraft (MNFI 1989), and Mackinac (MHA in 2005) county observations lack documentation. A second Iron Co. record from 2011 with a photo of a road-killed specimen was submitted to the MHA (record 3183). We encourage submission of the photo to a museum collection. Holman's notes indicate that his Alger, Dickinson, and Menominee county records were inferred from Casper (2002), and the Delta Co. record is observational. This species is absent from Isle Royale (Casper 2008).

Accepted: Dickinson, Marquette, Menominee counties.

Suppressed: Iron (MHA photo record requires museum deposition), Delta, Schoolcraft (observations only), Alger (no records) counties.

***GLYPTEMYS INSCULPTA* (Wood Turtle).** Baraga Co.: Ottawa National Forest, Sturgeon River (46.5°N, 88.6°W,). 25 May 2012. Gary S. Casper, Kristina M. Kroening. UMMZ 243381. Verified by Gregory Schneider. New county record. Dried shell found on bluff. Iron Co.: Ottawa National Forest, Tamarack River (46.2°N, 88.9°W). 9 June 2010. Gary S. Casper. UMMZ 1235 (photo). Verified by Gregory Schneider. New county record.

A fairly common species in the western U.P., but sensitive to road mortality, collecting, and riparian habitat degradation. An Alger Co. specimen is available (MPM 33960), but the circumstances raise questions. The dried shell was found on high ground in Pictured Rocks National Lakeshore in 1990 by Jeffrey S. Davis. It is stained brown as is common in turtles from the tannin rich streams of the Lake Michigan drainage to the south (in Schoolcraft and a portion of Alger counties). No other Wood Turtles have been found despite extensive surveys in Alger Co. by us and Jeffrey S. Davis. Bald Eagles are known to prey on turtles and bring them to their nests, discarding the shells (Mabie et al. 1995), and it is possible this individual was transported this way. Until additional records are obtained for Alger Co., we treat their presence there as hypothetical.

A 1997 Chippewa Co. record lacks documentation (MNFI 1997). We provide the first voucher specimens (salvaged shell and photo) here for Baraga and Iron counties, with the Iron Co. voucher supporting 1995 (MNFI 1995) and 1998 observations (MNFI 1998b). Two recent Marquette Co. photo records (MHA from 2008 and 2011) require action for meeting SSAR standards. Interestingly, earlier Marquette Co. observations from 1998 and 2005 (MNFI 1998a, 2005) are recognized as a new county record but not thus documented by depositing photo vouchers. Accordingly, we reluctantly treat Marquette Co. as having only observational data although photo vouchers are clearly available and need only be properly deposited and published. Holman's notes indicate that his Luce and Mackinac county dots were inferred from Casper (2002), and Chippewa and Marquette counties are observational. This species is absent from Isle Royale (Casper 2008).

Accepted: Baraga, Delta, Dickinson, Gogebic, Houghton, Iron, Menominee, Ontonagon, and Schoolcraft counties.

Suppressed: Alger (questionable). Chippewa, Marquette (MHA photos require deposition). Luce, and Mackinac (no records) counties.

***GRAPTEMYS GEOGRAPHICA* (Northern Map Turtle).** Holman's notes attribute his Dickinson Co. dot to J. H. Harding. Harding (pers. comm.) recalled an observation from Dickinson Co. by a credible naturalist in the late 1980s or early 1990s. There are no records for this species from adjacent Florence and Marinette counties in Wisconsin (Vogt 1981; Casper 1996). Harding (*op. cit.*) also personally saw one in the Manistique River in Schoolcraft Co. "years ago," but does not consider them native there. However, a small male was taken in a fyke net in Swan Lake, Schoolcraft Co., in 1975 (UMMZ 142771). This is an isolated lake near the Indian River, which drains into the Manistique River. We accept Schoolcraft Co. based on this voucher but recognize that questions remain over whether or not a population is native and/or established. This species is absent from Isle Royale (Casper 2008).

Accepted: Schoolcraft.

Suppressed: Dickinson (observational only).

New: None.

***TRACHEMYS SCRIPTA ELEGANS* (Red-eared Slider).** Iron Co.: (introduced) Ottawa National Forest, in outflow creek north end of Lake Ottawa (46.0949°N, 88.7524°N). 22 June 2010. Ryne D. and Jenny L. Rutherford. FMNH 281240. Verified by Alan Resetar. New county record. Old adult male.

We provide a new Iron Co. voucher collected in 2010, interpreted as a translocation, as it is far outside the normal range and this species is not considered native to the U.P. (Holman 1994). It is absent from Isle Royale (Casper 2008).

SQUAMATA — LIZARDS

***PLESTIODON FASCIATUS* (Common Five-lined Skink).** This lizard is common in and around granite bedrock glades northwest of Marquette to the Huron Mountains and in a variety of open and edge habitats in Menominee and southwestern Delta counties, including sandy beach ridges, forest edges, and gravel pits (RDR, pers. obs.). We also have a report for Mackinac Co. (Tinkle et al. 1979) but without verification. Holman's notes indicate that dots for Alger and Dickinson counties were inferred from Casper (2002). This species is absent from Isle Royale (Casper 2008).

Accepted: Delta, Marquette, and Menominee counties.

Suppressed: Alger and Dickinson (no records) counties.

New: None.

SQUAMATA — SNAKES

***COLUBER CONSTRICTOR* (North American Racer).** Holman (2004) indicates a "relict" population in Menominee Co., but we are uncertain about the information this is based upon, and the narrative in Holman (2012) simply states it occurs in the county. J. Harding has no data for Menominee Co. (pers. comm.), and there are no records for adjacent Wisconsin counties (Casper 1996). Absent documentation, we treat this record as hypothetical.

Accepted: None.

Suppressed: Menominee (no records).

New: None.

TABLE 1. Salamander matrix. AMLA = *Ambystoma laterale*, AMMA = *Ambystoma maculatum*, HESC = *Hemidactylium scutatum*, NEMA = *Necturus maculosus*, NOVI = *Notophthalmus viridescens*, PLCI = *Plethodon cinereus*. (P) = photo.

***DIADOPHIS PUNCTATUS EDWARDSII* (Northern Ring-necked Snake)**. BARAGA CO.: Ottawa National Forest, Evergreen Lake (46.7111°N, 88.0619°W). 10 July 2010. Ryne D. and Jenny L. Rutherford. FMNH 281235. Verified by Alan Resetar.. New county record. CHIPPEWA CO.: Northeast side of Caribou Lake (46.0038°N, 83.9872°W,). 15 September 2014. Jenny L., Cypress, and Ryne D. Rutherford. UMMZ 243467. Verified by Gregory Schneider. New county record. Under cobble along forest edge. DICKINSON CO.: Sturgeon hydrodam (45.7424°N, 87.8635°W). 9 September 2014. Jenny L., Cypress, and Ryne D. Rutherford. UMMZ 243466. Verified by Gregory Schneider. New county record. Under rubber refuse along forest edge on a steep slope. HOUGHTON CO.: Ottawa National Forest, near FR1334 and railroad crossing (46.5660°N, 88.8230°W). 4 June 2013. Kristina M. Kroening, Gary S. Casper. UMMZ 243258. Verified by Gregory Schneider. New county record. In downed woody debris. KEWEENAW CO.: Along Hwy 26 near Lower Silver River Road (47.4665°N 88.0669°W). 19 May 2011. Ryne D. and Jenny L. Rutherford. UMMZ 243259. Verified by Gregory Schneider. New county record. Found dead alongside rock. MENOMINEE CO.: Along Hwy 366 ca. 0.31 km E of Hwy 360 (45.5228°N, 87.4313°W). 12 August 2014. Ryne D. Rutherford. UMMZ 243468. Verified by Gregory Schneider. New county record. Found crawling over rocks in a gravel pit.

A locally abundant snake, especially in areas with exfoliating rock (granitic, volcanic, and sedimentary bedrock outcrops, exposures of coarse glacial till). Probably distributed throughout the U.P. where suitable habitat is available, but vouchers are lacking for two counties. Holman's notes indicate dots for Alger and Luce counties were inferred from Casper (2002). Jeffrey S. Davis reported Alger Co. observations from Grand Island and the Kingston Plains area (pers. comm.; Casper 2005). A 2011 photo of a road-killed specimen from Dickinson Co., posted anonymously on the MHA website, lacks sufficient data. This species is absent from Isle Royale (Casper 2008).

Accepted: Baraga, Chippewa, Delta, Dickinson, Gogebic, Houghton, Iron, Keweenaw, Mackinac, Marquette, Menominee, Ontonagon, and Schoolcraft counties.

Notes:
Blank cells have no supporting vouchers.
Coluber constrictor is suppressed from Menominee Co.
Heterodon platirhinos - Menominee Co. earliest year (1924 - FMNH 5998), earliest verified (1940 - UMMZ 89502-3).
Regina septemvittata - Mackinac Co. earliest year (1942 - UMMZ 91994, 92232), earliest verified (1942 - UMMZ 91994, 92232).
Sistrurus catenatus - Mackinac Co. earliest year (1926 - UMMZ 67714), earliest verified (1926 - UMMZ 67714).
Thamnophis sauritus septentrionalis - Mackinac Co. earliest year (1956 - UMMZ 114175), earliest verified (1956 - UMMZ 114175).

Suppressed: Alger (observational only) and Luce (no records) counties.

***HETERODON PLATIRHINOS* (Eastern Hog-nosed Snake).** Known only from extreme southern Menominee Co. in the U.P., where it is at its range limit. The last verified museum records are from 1940, but we (RDR) reconfirmed presence in 2014 with a road-killed specimen (UMMZ 243469). This species is absent from Isle Royale (Casper 2008).

Accepted: Menominee.
Suppressed: None.
New: None.

***LAMPROPELTIS TRIANGULUM TRIANGULUM* (Eastern Milksnake).** Verified in only two U.P. counties. MHA reports an observation from Dickinson Co. This species is absent from Isle Royale (Casper 2008).

Accepted: Mackinac, Marquette.
Suppressed: None.
New: None.

***NERODIA SIPEDON SIPEDON* (Northern Watersnake).** Confirmed in five counties. A specimen originally listed as from Gogebic Co. (UMMZ 75850) was determined to have actually been collected in Preston Co., West Virginia, in 1932. Holman's notes indicate dots for Gogebic and Luce counties were inferred from Casper (2002), while attribution for Menominee and Ontonagon

county dots is unspecified. This species is absent from Isle Royale (Casper 2008).

Accepted: Alger, Chippewa, Delta, Mackinac, Schoolcraft.

Suppressed: Gogebic, Luce, Menominee, Ontonagon (no records).

New: None.

***OPHEODRYS VERNALIS* (Smooth Greensnake).** Houghton Co.: Ottawa National Forest, along FR 2276 (46.6808°N, 88.7335°W). 30 June 2010. Gary S Casper, Jason M. Dare. FMNH 281096. Verified by Alan Resetar. New county record. Under plywood board. Ontonagon Co. Ottawa National Forest, Bond Falls Flowage at Little Falls (46.3794°N, 89.1006°W). 18 July 2010. Gary S. Casper, Thomas G. Anton, David Mauger. FMNH 281098. Verified by Alan Resetar. New county record. In fractured basalt and woody debris in large grassed meadow of drained flowage bed.

Verified in all U.P. counties except for Keweenaw. The distribution appears to have some gaps in the western U.P. (unpubl. data), which are not readily apparent from county level maps. We provide two new county records here. Holman's notes indicate his Keweenaw Co. dot was inferred from Casper (2002). This species is absent from Isle Royale (Casper 2008).

Accepted: All counties except Keweenaw.

Suppressed: Keweenaw Co. (no records).

***PANTHEROPHIS VULPINUS* (Western Foxsnake).** Alger Co.: (reconfirmed) T46N R17W Sec. 30, Cusino Station (46.445°N, 86.35861°W). 20 July 1957. O. Hammerberg. UMMZ 117184. Verified by Gregory Schneider. New county record.

This species is verified in several central U.P. counties, but purported records from the western counties have not been confirmed. Extensive sampling throughout the Ottawa National Forest has yielded negative results, with the Iron River area being the furthest west occurrence known (GSC and RDR, unpubl. data, 2010–2014). Ruthven et al. (1928) included solid dots for Ontonagon and Alger counties, but we have been unable to locate the specimens, suggesting that they were later re-determined, or are lost. We leave Ontonagon as suppressed, but the earliest (1957) specimen we could find for Alger Co. reconfirms that record (first published here). Holman's notes indicate dots for Baraga, Gogebic, Houghton, Keweenaw, and Ontonagon counties were inferred from Casper (2002). This species is absent from Isle Royale (Casper 2008).

Accepted: Alger, Delta, Dickinson, Iron, Marquette, Menominee, and Schoolcraft counties.

Suppressed: Baraga, Gogebic, Houghton, Keweenaw, and Ontonagon (no records) counties.

***REGINA SEPTEMVITTATA* (Queen Snake).** This species is known only from a 1948 record on Bois Blanc Island in Lake Huron, which, while politically in Mackinac Co., has more biological affinity with the Lower Peninsula than the U.P. Surveys are needed to determine if this species is still extant there.

Accepted: Mackinac.

Suppressed: None.

New: None.

***SISTRURUS CATENATUS* (Eastern Massasauga).** This species is known only from Bois Blanc Island in Lake Huron, which, although in Mackinac Co., has more biological affinity with the Lower Peninsula than the U.P.

Accepted: Mackinac.

Suppressed: None.

New: None.

***STORERIA DEKAYI* (Dekay's Brownsnake).** Delta Co.: West side of Point Detour (45.6045°N, 86.6161°W). 31 August 2014. Jenny L., Cypress and Ryne D. Rutherford. UMMZ 243470. Verified by Gregory Schneider. New county record. Under limestone slab in shoreline alvar adjacent to upland cedar forest. Menominee Co. The Oxbow, Menominee River (45.3692°N, 87.8754°W). 26 June 2009. Ryne D. and Jenny L. Rutherford. UMMZ 1243–4 (photo). Verified by Gregory Schneider. New county record. On moist soil along river.

This species is verified only from Delta, Menominee, and Schoolcraft counties, two of which are newly presented here. Holman's notes indicate his Keweenaw County dot was inferred from Casper (2002), and Marquette Co. is without any specific source. This species is absent from Isle Royale (Casper 2008).

Accepted: Delta, Menominee, and and Schoolcraft counties.

Suppressed: Keweenaw and Marquette counties (no records).

***STORERIA OCCIPITOMACULATA OCCIPITOMACULATA* (Northern Red-bellied Snake).** Menominee Co.: (reconfirmed) ca. 1.6 km S of Harris (45.69°N, 87.35°W). 20 August 1939. Collector unknown. UMMZ 85536. Verified by Gregory Schneider.

This is the most common snake in the U.P., verified from every county and Isle Royale (Casper 2008). Holman (2012) omitted a dot from Menominee Co., but the dot is plotted in his notes, and mentioned by Johnson (1965), so we suspect this omission was a transcription error, given the ready availability of specimens from this county (MSUM, UMMZ). We provide voucher confirmation here.

Accepted: All counties.

Suppressed: None.

***THAMNOPHIS SAURITUS SEPTENTRIONALIS* (Northern Ribbonsnake).** Verified only from Bois Blanc Island in Lake Huron, which, while politically in Mackinac Co., has more biological affinity with the Lower Peninsula than with the U.P. Holman (2012) also reports them from Drummond Island, Chippewa Co., without providing a source (a dot was placed only on the island). The Keweenaw Co. record from Isle Royale is based upon a specimen collected by Dr. A. E. Foote in the early 1900s and has been lost, and is considered an error (Johnson 1965; Casper 2008). A MHA observational record from Marquette Co. lacks documentation.

Accepted: Mackinac.

Suppressed: Chippewa and Keweenaw counties (see above).

New: None.

***THAMNOPHIS SIRTALIS* (Common Gartersnake).** Menominee Co.: (reconfirmed) 16.1 km NE of Menominee (45.3°N, 87.5°W). 1939. H. Vander Schalie. UMMZ 85583. Verified by Gregory Schneider. New county record.

The second most common snake in the U.P. (after *S. occipitomaculata*), confirmed in every county. Holman (2012) omitted a dot from Menominee Co., but the dot is plotted in his notes, and mentioned by Johnson (1965), so we suspect this omission was a transcription error, given the ready availability of specimens from this county (MSUM, UMMZ). We provide voucher confirmation here. This species is verified from Isle Royale (Casper 2008, Mooi et al. 2011).

Accepted: All counties.
Suppressed: None.

Acknowledgments.—We especially thank James Harding (MSUM) for finding and sharing Holman's notes, and he and Gregory Schneider (UMMZ) for sharing their extensive insights and assisting with collections access and verifications. The following collections managers provided data, collections access, and/or assisted with specimen verifications, for which we are very grateful: Laura Abraczinskas and Barbara Lundrigan (MSUM), Julia Colby (MPM), Thomas C. Erdman (UWGB), Ned S. Gilmore (ANSP), James Poindexter II (USNM), Alan Resetar (FMNH), Angela Riedel (CMU), Stephen P. Rogers (CM), and David B. Wake (MVZ). We thank Yu Man Lee (MNFI), David A. Mifsud (MHS), and Lori G. Sargent (Michigan DNR) for providing data from state programs. We also thank the following folks for general cooperation, dedication, grant administration, and providing personal insights and data: Jeffrey A. Soltesz and Brian Bogaczyk (Ottawa National Forest); William T. Route, Ulf Gafvert, and Joan Elias (National Park Service Great Lakes Network Office); Jerry Belant, Cindy Heyd, Lora M. Loope, and Leah Kainulainen (Pictured Rocks National Lakeshore); Paul Brown and Mark C. Romanski (Isle Royale National Park); Ann McCammon-Soltis (Great Lakes Indian Fish and Wildlife Commission); Jeffrey S. Davis, and the many other persons contributing herptile data for the U.P. to various programs.

This study was supported in part by funding from the National Park Service (Great Lakes Inventory and Monitoring Network, Midwest Region Park Steward Program), National Fish and Wildlife Foundation Sustain Our Great Lakes Program (to Lakehead University, Thunder Bay, Ontario), U.S. Environmental Protection Agency Great Lakes Restoration Initiative (to the Ottawa National Forest, Ironwood, Michigan; and to the Great Lakes Indian Fish and Wildlife Commission, Odanah, Wisconsin). Collecting by the authors was performed under Michigan DNR, Ottawa National Forest, Isle Royale National Park, and Pictured Rocks National Lakeshore Scientific Collecting permits.

NATURAL HISTORY NOTES

CAUDATA — SALAMANDERS

***AMBYSTOMA VELASCI* (Plateau Tiger Salamander). MORTALITY.** *Ambystoma velasci* is a salamander endemic to Mexico, and has been reported to feed on any vertebrates and invertebrates that can possibly be swallowed (Lemos-Espinal and Dixon 2013. Amphibians and Reptiles of San Luis Potosí. Eagle Mountain Publishing, LC, Eagle Mountain, Utah. 300 pp.), including conspecifics (Vite-Silva et al. 2009. Bull. Maryland Herpetol. Soc. 45:1). However, herein we report a case of a fatality of *A. velasci* due to the failed consumption of a dragonfly naiad.

At 1455 h on 20 September 2012, a male *A. velasci* (SVL = 66 mm) was found freshly dead on the edge of a pond (Fig. 1A) located in the vicinity of El Ocotoreo, municipality of Xichú, Guanajuato, Mexico (21.3143°N, 100.1088°W, WGS84, 2252 m elev.). After a closer examination, we found a live dragonfly naiad (Odonata) lodged deeply within its mouth (Fig. 1B). We speculate that the salamander died by the failure to subdue, kill, and pass the lodged dragonfly naiad deeper into the digestive tract. Although dragonfly naiads are very common in ponds and similar areas where *A. velasci* is present, it still remains to be studied what proportions of them occur in the diet of *A. velasci*.

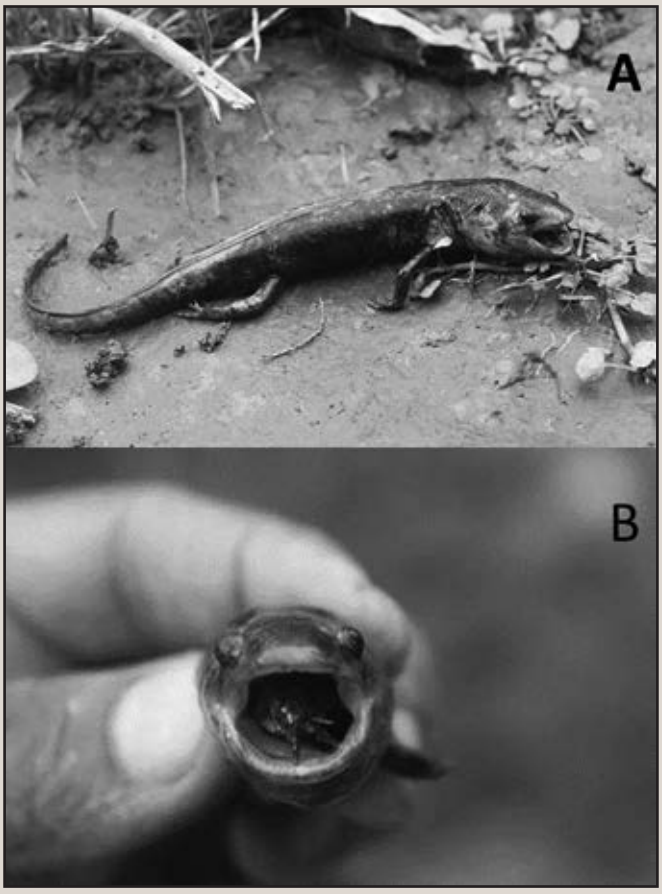

PHOTO BY ADRIAN LEYTE-MANRIQUE

FIG. 1. A freshly dead *Ambystoma velasci* with a live dragonfly naiad lodged in its mouth.

Special thanks are due to Efrén Hernández-Navarro and José Antonio Corona for their assistance in the field, and to Larry David Wilson for the improvement of this note.

ADRIAN LEYTE-MANRIQUE, Laboratorio de Biología, Departamento de Innovación Agrícola Sustentable, Instituto Tecnológico Superior de Salvatierra. Manuel Gómez Morín # 300, C.P. 39800, Col. Janicho, Salvatierra, Guanajuato, México (e-mail: aleyteman@gmail.com); **JUAN PABLO MORALES-CASTORENA**, Licenciatura en Biología, Instituto Tecnológico Superior de Irapuato. ***BOLITOGLOSSA CELAQUE* (Celaque Climbing Salamander). DIET.** The plethodontid salamander *Bolitoglossa celaque* inhabits the highlands of southwestern Honduras in the departments of Íntibuca, La Paz, and Lempira (McCranie and Castañeda 2007. Guia de Campo de los Anfibios de Honduras. Bibliomania!, Salt Lake City, Utah. 304 pp.), and is considered Endangered by the IUCN (Townsend and Wilson 2010. *In* Wilson et al. [eds.], Conservation of Mesoamerican Amphibians and Reptiles, pp. 461–486. Eagle Mountain Publishing, Eagle Mountain, Utah). No information has previously been reported regarding the diet of this species (McCranie and Wilson 1993. Herpetologica 49:1–15; McCranie and Wilson 2002. Amphibians of Honduras. Society for the Study of Amphibians and Reptiles, New York. 625 pp.; McCranie and Castañeda 2007, *op. cit.*).

We examined dietary items from ten preserved specimens of *B. celaque*: eight individuals (five juveniles [UF 156457, 156459, 156461, 156467–156468] and two females [UF 156463, 156465]) from Parque Nacional Celaque, Dept. Lempira (14.558°N, 88.674°W, WGS84, 2575 m elev.); one juvenile (UF 156484) from El Rodeo, Dept. Íntibuca (14.461°N, 88.156°W, WGS84, 2170 m elev.); and one juvenile (UF 156473) from Reserva Biologíca Guajiquiro, Dept. La Paz (14.145°N, 87.837°W, WGS84, 2160 m elev.). Dietary items were flushed from the mouth, throat, and stomachs of preserved specimens without dissection, stored in 70% EtOH, and examined using light stereomicroscopy. Identification was done to the lowest taxonomic order possible based on sample condition using the descriptors and keys provided by Borror and White (1970. A Field Guide to Insects: America North of Mexico. Houghton Mifflin Co., Boston, Massachusetts. 404 pp.).

Twenty-two individual diet items were identified, representing the insect orders Coleoptera (36.4%) and Hymenoptera (13.6%), arachnid orders Acari (18.2%) and Araneae (9.1%), and other arthropods represented by the class Diplopoda (9.1%), and order Isopoda (4.5%). Eight coleopteran specimens represented

the majority of identified dietary samples; two specimens were larvae. Two adult coleopteran were identified to family representing Circulionidae and Staphylinidae. Hymenoptera were primarily identified based on wing and head morphology. Arachnida was represented by six specimens (27.3%), primarily from the subclass Acari. Within the order Araneae, one specimen could be identified to family Salticidae based on morphology. Diplopoda were identified based on the presence of two leg attachment points per segment and Isopoda (4.5%) based on morphology, color and patterning.

Five individuals contained multiple prey items. The highest prey diversity was observed in a juvenile (UF 156457, SVL = 23.2 mm) containing five unique prey items representing Coleoptera (Circulionidae), Diplopoda, Acari, Hymenoptera, and an unidentified larva. A single juvenile from Intibuca (UF 156484, SVL = 27.8 mm) contained four unique prey items, including Acari, Araneae, Hymenoptera, and Diplopoda. Another juvenile from Lempira (UF 156459, SVL = 31.9 mm) had three unique prey items from the Order Coleoptera including a larva and two adults (one Family Staphylinidae). One juvenile (UF 156473, SVL = 33.6 mm) from La Paz, one coleopteran and one hymenopteran (Family Sphecidae). A juvenile (UF 156468, SVL = 21.2 mm) from Lempira contained two Acari.

We thank T. J. Firneno, Timothy Hummel, D. J. McNeil, and Melissa Medina for providing assistance in the lab during the examination of diet items.

MICHAEL W. ITGEN (e-mail: m.w.itgen@iup.edu), **ALEXANDER J. HESS** (e-mail: ajhess44@gmail.com), **ELLEN L. TEYGART** (e-mail: e.teygart@iup.edu), and **JOSIAH H. TOWNSEND**, Department of Biology, Indiana University of Pennsylvania, Indiana, Pennsylvania 15705-1081, USA (e-mail: josiah.townsend@iup.edu).

***BOLITOGLOSSA DIAPHORA* (El Cusuco Salamander). DIET.** The plethodontid salamander *Bolitoglossa diaphora* is endemic to Parque Nacional Cusuco in the Sierra de Omoa in northwestern Honduras, and is considered Critically Endangered due to its limited distribution and the infrequency with which it is encountered (Townsend and Wilson 2008. Guide to the Amphibians and Reptiles of Cusuco National Park, Honduras. Bibliomania!, Salt Lake City, Utah. 322 pp.). Nothing has previously been reported regarding the diet of this species (McCranie and Wilson 1995. J. Herpetol. 29: 447–452; McCranie and Wilson. 2002. The Amphibians of Honduras. Society for the Study of Amphibians and Reptiles, New York. 625 pp.; Townsend and Wilson 2008, *op. cit.*).

We examined dietary items of nine preserved specimens of *B. diaphora* from Parque Nacional Cusuco, Dept. Cortés (15.495°N, 88.211°W, WGS84, 1520–1990 m elev.): three males (UF 144082, UF 156491, USNM 335046), five females (UF 144085, UF 156492–93, USNM 335047–8), and a single juvenile (UF 142739). Dietary samples were flushed from the mouth, throat, and stomachs of preserved specimens without dissection, stored in 70% EtOH, and examined using light stereomicroscopy. The identification of prey items was done to the lowest taxonomic level based on body parts and using descriptors and keys (Borror and White 1970. A Field Guide to Insects: America North of Mexico. Houghton Mifflin Co., Boston, Massachusetts. 404 pp.).

We found 14 individual prey items comprised of insect orders Hymenoptera (64.3%) and Coleoptera (7.13%), and two classes of arthropods: Arachnida (14.3%) and Diplopoda (14.3%). Seven of the Hymenoptera diet specimens were identified to the Family Formicidae and a single sample into the Family Sphecidae. The two arachnid samples represented the orders Pseudoscorpionidae and Salticidae. Among *B. diaphora*, we found the maximum number of prey items within a single individual to be five. The female (UF 156492, SVL = 30.2 mm) with the largest sample had a single pseudoscorpionid and four Hymenoptera (Formicidae). One female (UF 144085, SVL = 41.9 mm) contained a single Hymenoptera (Formicidae) and a Coleopteran; another female (UF 335047, SVL = 35.7 mm) had consumed a Hymenoptera (Formicidae) and a Diplopoda.

We thank T. J. Firneno, Timothy Hummel, D. J. McNeil, and Melissa Medina for providing assistance in the lab during the examination of diet items, and Roy W. McDiarmid and Steve W. Gotte (USNM) for loaning the diet items recovered specimens in that collection.

TOWNSEND** (e-mail: josiah.townsend@iup.edu), Department of Biology, Indiana University of Pennsylvania, Indiana, Pennsylvania 15705-1081, USA.

***DESMOGNATHUS ABDITUS* (Cumberland Dusky Salamander). PREDATION.** On 12 July 2015, we moved a small streamside rock along a tributary of Tennessee's Obed River, Morgan Co., Tennessee, USA (36.0820°N, 84.7610°W, WGS84) to discover a small adult *Desmognathus abditus* being consumed by an adult *Diadophis punctatus* (Ring-necked Snake). After being disturbed, the snake regurgitated the still-living salamander. *Diadophis punctatus* is a frequent predator of plethodontid salamanders, including *Desmognathus* (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, Washington, DC. 668 pp.), but this is the first documented occurrence of predation of *Desmognathus abditus*, or any other species in the *Desmognathus ochrophaeus* complex, by *Diadophis punctatus*. Forester (1978. J. Herpetol. 12:537–541) conducted experimental encounters between *Diadophis punctatus* and *Desmognathus ochrophaeus* (now *Desmognathus ocoee*, Ocoee Dusky Salamander) and demonstrated attempted predation by the former and a strong flight response in the latter. Cupp (1994. Anim. Behav. 48:232–235) showed that *Desmognathus ochrophaeus* avoid substrates marked with the scent of *Diadophis punctatus*. However, we are not aware of any prior field observations of predation of members of the *Desmognathus ochrophaeus* complex by *Diadophis punctatus*.

FIG. 1. Small adult *Desmognathus abditus* being consumed by an adult *Diadophis punctatus*.

PIERSON**, Department of Ecology and Evolutionary Biology, University of Tennessee, Knoxville, Tennessee, 37996, USA (e-mail: tpierso1@vols.utk.edu).

***DESMOGNATHUS QUADRAMACULATUS* (Black-bellied Salamander). MAXIMUM CLUTCH SIZE.** *Desmognathus quadramaculatus* is a semi-aquatic plethodontid of the southern Appalachians in the southeastern USA. The reproductive ecology of this species has been studied in sites throughout its range (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, DC. 587 pp.; Camp et al. 2000. Can. J. Zool. 78:1712–1722; Camp et al. 2002. Herpetologica 58:471–484). Average clutch size is typically 31–54, depending on locality (Petranka 1998, *op. cit.*). A previous note reported a maximum clutch size of 82 from northeastern Georgia, USA (Camp et al. 2010. Herpetol. Rev. 41:330). In the late morning of 01 June 2013 we discovered two *D. quadramaculatus* clutches attended by females (both escaped and were not captured) under small rocks (~15 × 8 × 5 cm) in a tributary of the Toccoa River in Union Co., Georgia, USA (34.7589°N, 84.0310°W; WGS84). We counted 71 eggs in the smaller clutch and 105 eggs in the larger clutch, which now represents the maximum clutch size for this species. We returned the rocks carefully to their position in the stream and returned to check the rocks five hours later to determine if the females returned to their clutch. The female attending the larger clutch had returned, but the other had not.

***EURYCEA NAUFRAGIA* (Georgetown Salamander). BEHAVIOR.** *Eurycea naufragia* is a neotenic spring and cave dwelling plethodontid salamander. This species is known from approximately 15 sites from the San Gabriel River watershed in Texas, an area that is undergoing rapid urbanization. The limited range of the species and its restricted habitats led to its recent listing as a threatened species. From 22 March to 03 May 2012, salamanders were trapped at a permanent spring in Williamson Co., Texas, USA (precise locality withheld due to conservation concerns). Each trap consisted of a fine mesh net 76.2 cm long with a 16.5 cm opening supported by wire at one end and the other end attached to a capped 5.08 × 29.2 cm PVC pipe, with a mesh covered opening on the side to allow water flow. Each week we conducted one diurnal and one nocturnal sampling event separated by 24 to 48 h. We randomized whether diurnal or nocturnal trapping was conducted first within each week. Three traps were placed at the same locations within the spring run (at the spring outflow, 1 m and 7 m downstream) for each sample. Diurnal sampling was conducted from 0700 h to 1900 h and nocturnal sampling from 1900 h to 0700 h. Based on a visual estimate of total length (following Bowles et al. 2006. Hydrobiologia 553:111–120; Pierce et al. 2010. Southwest. Nat. 55:296–301; Bendik et al. 2014. Herpetol. Conserv. Biol. 9:206–222), each salamander was assigned to one of two size classes: juvenile (<5.1 cm total length) or adult (>5.1 cm total length). After processing, all salamanders were released back into the spring run at point of capture. For comparison of nocturnal and diurnal samples, we combined all salamanders captured in the three traps during a sampling event.

We captured more salamanders during the nocturnal sampling events (5.71 ± 2.56 salamanders, mean ± SD) than during diurnal sampling events (1.14 ± 1.07). These differences, however, were not consistent across the two size classes. We captured more juvenile salamanders in nocturnal sampling events (4.57 ± 2.30) than in diurnal sampling events (0.14 ± 0.38). There was no significant difference in number of adult salamanders captured during nocturnal (1.14 ± 1.46) and diurnal sampling events (1.00 ± 1.15). The total number of salamanders that we captured in this study (N = 48) was relatively low, but the results were nevertheless straightforward and suggest that juvenile *E. naufragia* salamanders are more active at night.

A number of other studies have concluded that terrestrial salamanders are more active at night (e.g., Hairston 1949. Ecol. Monogr. 19:47–73; Connette et al. 2011. Southeast. Nat. 10:109–120). However, only a few studies have examined daily activity in aquatic life stages and none have examined permanently aquatic species. A study on activity patterns of aquatic stream salamander larvae (*Desmognathus fuscus* [Northern Dusky Salamander], *Eurycea cirrigera* [Southern Two-lined Salamander], *E. guttolineata* [Three-lined Salamander], *Pseudotriton montanus* [Mud Salamander], and *P. ruber* [Red Salamander]) found higher nighttime activity (Connette et al. 2011, *op. cit.*). In a study of *E. bislineata*, aquatic larvae were more active at night (Petranka 1984. J. Herpetol. 18:48–55). Contrary to the current study, densities of *D. fuscus* aquatic larvae were similar during day and night (Orser and Shure 1975. Am. Midl. Nat. 93: 403–410).

Our observations suggest that juvenile *E. naufragia* are more active at night and that nocturnal surveys will result in higher abundance observations for this life stage. These conclusions are limited by only sampling during a single season and using a single survey method (traps). Nevertheless our observations suggest that investigators surveying larval or aquatic salamanders should be aware of potential differences in diurnal and nocturnal activity patterns that may affect survey results.

We thank the property owners for permission to survey salamanders on their land. The Texas Parks and Wildlife provided a scientific research permit for study of the salamanders. This study complied with all applicable institutional animal care guidelines.

KIRA D. McENTIRE (e-mail: mcentire.kd@gmail.com) and **BENJAMIN A. PIERCE**, Department of Biology, Southwestern University, Georgetown, Texas, 78626, USA. Current address of KDM: Warnell School of Forestry and Natural Resources, University of Georgia, Athens, Georgia 30602, USA.

***PLETHODON CINEREUS* (Eastern Red-backed Salamander). MORPHOLOGY.** Two color morphs are common in *Plethodon cinereus*, striped and unstriped (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 587 pp.). Both morphs are present in Ohio, with the northwestern portion of the state containing a high frequency of the unstriped morph, which is typically far less common than the striped morph. South Bass Island, part of the Lake Erie archipelago, contains a well-documented monomorphic unstriped population (Pfingsten and Walker 1978. J. Herpetol. 12:163–167;

FIG. 1. Striped *Plethodon cinereus* found within a monomorphic unstriped population on South Bass Island, Ohio. This individual represents the only striped individual collected from the island.

Hantak, pers. obs.). To date, a single striped individual has been discovered on South Bass Island (Reichenbach 1981. Herpetol. Rev. 12:53) among hundreds of unstriped *P. cinereus* collected over decades (Pfingsten and Walker 1978, *op. cit.*; Reichenbach 1981, *op. cit.*; Hantak, pers. obs.). Thirty-six years after the sighting of the first striped individual on South Bass Island (Reichenbach 1979, pers. obs.), a second individual has been found (Fig. 1). It was discovered on 29 April 2015 on the Heineman property, South Bass Island, Ottawa Co., Ohio, USA (41.6465°N, 82.8234°W, WGS84). The individual was a juvenile (SVL = 22.75 mm; 0.26 g), and was found with three unstriped juveniles under a decaying log. This specimen was collected and preserved at Ohio University (MMH459), unlike the previous individual, which was only photographed. The genetics underlying the striped/unstriped color polymorphism of *P. cinereus* are currently not well understood; however, discordant results by Highton (1959. Copeia 1959:33–37; Highton 1975. Genetics 80:363–374) suggest that the genetics of the polymorphism may be geographically variable. Whether the striped morphs occur on South Bass Island as a consequence of a recent, novel mutation, or whether these individuals reflect the retention of an ancestral polymorphism, is not known.

We thank the Heineman family for allowing us to work on their property.

HICKERSON** (e-mail: chickerson@jcu.edu), **CARL D. ANTHONY**, Department of Biology, John Carroll University, University Heights, Ohio 44118, USA (e-mail: canthony@jcu.edu).

ANURA — FROGS

HYLA CHRYSOSCELIS **(Cope's Gray Treefrog) ×** ***HYLA CINEREA*** **(Green Treefrog). PUTATIVE NATURAL HYBRID.** Naturally occurring hybrid treefrogs have been occasionally found in the eastern United States. However, these hybrids are almost always between members of the same species group (e.g., Gerhardt 1974. Behaviour 49:130–151; Gerhardt et al. 1980. Copeia 1980:577–584; but see Anderson and Moler 1986. Copeia 1986:70–76). When *Hyla cinerea* group individuals were artificially crossed with *H. versicolor* group individuals, little reproductive success was achieved, and those tadpoles that survived to metamorphosis showed severe phenotypic abnormalities, and abnormal or incomplete sexual development (Mecham 1965. Am. Midl. Nat. 74:269–308).

At 2145 h on 10 June 2014 we heard an unusual anuran advertisement call along Bayou Manual Road in Sherburne Wildlife Management Area in the Atchafalaya Basin of south-central Louisiana, USA (30.4026°N, 91.6748°W, WGS84). The call resembled that from a *Hyla*, but did not sound like any of the *Hyla* species known from the area (*H. cinerea*, *H. chrysoscelis*, and *H. squirella* [Squirrel Treefrog]). The dominant calls at that time in the immediate vicinity were from *H. chrysoscelis*, with *H. cinerea*, *H. squirella*, *Incilius nebulifer* (Gulf Coast Toad), and *Gastrophryne carolinensis* (Eastern Narrow-mouthed Toad) each vocalizing to lesser degrees.

We collected the individual and brought it to the laboratory for further study. The treefrog measured 45 mm (SVL), with an elongated body shape, appearing more like *H. cinerea* than *H. chrysoscelis* in that regard. The subocular spot typical of *H. chrysoscelis* and the lateral stripe typical of *H. cinerea* were both absent. The overall pattern was mottled, and his coloring changed dramatically from predominantly green to predominantly brown. Even while green, however, his lower legs remained gray. The inner thighs did not exhibit bright flash colors typical of *H. chrysoscelis* (Fig. 1). Mecham (1965, *op. cit.*) described similar physical characteristics to our hybrid in his laboratory–crossed female *H. cinerea* and male *H. chrysoscelis* hybrid treefrogs. Reciprocal crosses between male *H. cinerea* and female *H. chrysoscelis* produced different patterns and resulted in a lack of one or both eyes (Mecham 1965, *op. cit.*).

The frog did not respond to calls of recordings of *H. cinerea* but did vocalize in response to the recorded call of *H. chrysoscelis*. We made a recording of the call of the putative hybrid in the laboratory at an air temperature of 24.6°C. We analyzed only four calls for measurements of the pulse duration, pulse interval, and pulse period by using the measurement tool in Sound Ruler ver. 0.9.6 (Gridi-Papp [ed.]. 2007. SoundRuler: Acoustic Analysis for Research and Teaching. http://soundruler.sourceforge.net). The dominant frequency was found using the dfreq function in the R package seewave (Sueur et al. 2008. Bioacoustics 18:213–226). The analyses produced the following means: pulse duration 0.0703 s, pulse period 0.1171 s, pulse interval 0.0473 s, and pulse rate 8.782 pulses/s. The mean dominant frequency of the calls was 2169 Hz (Fig. 2) which is higher than the 1906 Hz mean dominant frequency (at 25.0°C air temperature) of a laboratory-reared 38.2 mm hybrid resulting from a cross between a female *H. cinerea* and a male *H. chrysoscelis* (Fortman and Altig 1974. Herpetologica 30:221–234). The call had a frequency spectrum within the range of frequencies by the putative parent species (Fig. 2). The pulse rate, however, lay intermediate between the putative parent species (much faster than *H. cinerea*, and much slower than *H. chrysoscelis*). The full audio recording has been accessioned into the Macaulay Library with catalog number ML 148096 (http://macaulaylibrary.org/audio/148096).

Flow cytometry was used (Jenkins et al. 2011. Reproduction 141:55–65) to determine whether this individual had produced viable spermatozoa. The putative hybrid showed 3.4% (SE = 0.009) viable testicular cells in a suspension of the macerated testis compared to a normal male *H. chrysoscelis*, which had 44.3% (SE = 0.014) viable testicular cells. The testes of the putative hybrid were smaller (3.67 mm length, 1.44 mm width) compared to the normal *H. chrysoscelis* (4.5 mm length, 2.37 mm width). No

FIG. 1. Photos of the putative hybrid treefrog (*Hyla chrysoscelis* × *H. cinerea*) captured in the Atchafalaya Basin.

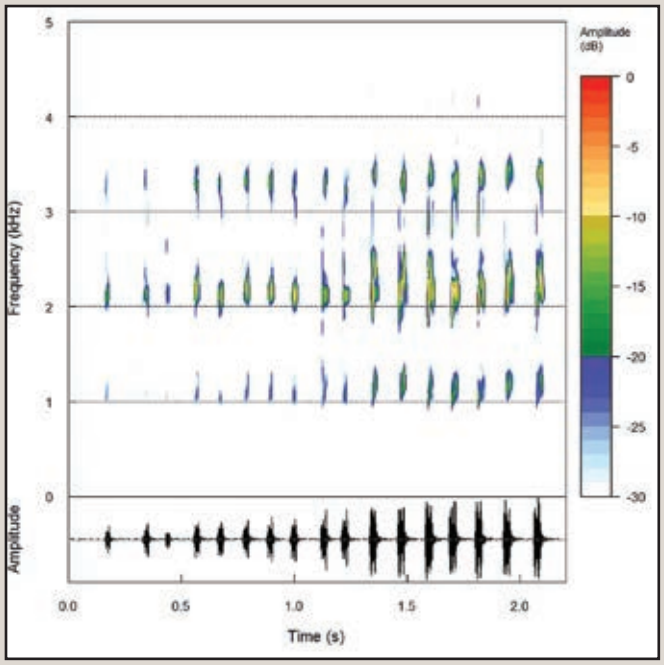

FIG. 2. Spectrogram of a call from the putative hybrid treefrog (*Hyla chrysoscelis* × *H. cinerea*) recorded at a distance of ca. 0.5 m from the calling frog at 24.6°C air temperature.

morphologically normal spermatozoa from the putative hybrid could be found by light microscopy, as cells appeared round and not like the cylindrical cells observed from the normal male *H. chrysoscelis*. Of the six adults Mecham (1965, *op. cit.*) sacrificed, all had either very small, rudimentary testes or lacked oviducts, and no sperm could be located in suspension. Mecham (1965,*op. cit.*) also stated that none of his grossly normal hybrids from female *H. cinerea* and male *H. chrysoscelis* that matured to adult size ever developed male throat pigment or definite vocal sacs, whereas this putative hybrid displayed both throat pigment and a vocal sac.

Flow cytometry was also used for high resolution nuclear DNA analysis to estimate the total genome size from nuclei of whole blood cells of the putative hybrid and the putative parental species, as species delineation can be discovered through the genetic complement. According to laboratory-generated genome size data from *H. chrysoscelis* and *H. cinerea* collected in the same area (J. Jenkins, unpubl. data), and data from the Animal Genome Size database (www.genomesize.com), the hybrid's diploid genomic complement was 9.8 pg, which was intermediate between the putative parental species.

Based on the phenotype, unusual call, small testes, lack of viable sperm, and intermediate genome size of this frog, we conclude that this treefrog is a hybrid of *H. chrysoscelis* and *H. cinerea*. Because the treefrog's characteristics are largely consistent with those described from laboratory crosses of male *H. chrysoscelis* and female *H. cinerea* (Meacham 1965, *op. cit.*), and because the reciprocal crosses typically resulted in high rates of abnormal early embryonic cleavage, very few tadpoles, and only one short-lived transformed individual (Pyburn and Kennedy 1960, *op. cit.*; Littlejohn 1961, *op. cit.*), we conclude that this individual is likely the result of a mating event between a male *H. chrysoscelis* and female *H. cinerea*. To our knowledge, natural hybrids between *H. chrysoscelis* and *H. cinerea* have not been previously reported (Dodd 2013. Frogs of the United States and Canada. Johns Hopkins University Press, Baltimore, Maryland. 982 pp.).

We thank Jeromi Hefner for collecting the reference frogs for the genetic component of this manuscript. We thank Jacqueline Perticone for laboratory assistance. Collection was authorized by LDWF permit # LNHP–14–071 and Sherburne WMA Special Use permit WL–Research–2008–02. The specimen was deposited in the LSU Museum of Natural Science (LSUMZ 99024). All handling of animals was conducted in accordance with approved IACUC protocols. Any use of trade, product, or firm names is for descriptive purposes only and does not imply endorsement by the U.S. Government. This is contribution number 483 of the U.S. Geological Survey Amphibian Research and Monitoring Initiative (ARMI).

***HYPSIBOAS PULCHELLUS* (Montevideo Tree Frog, Ranita de Zarzal). PREDATION.** Predation is one of the main causes of mortality in natural amphibian populations and may occur in any stage of the life cycle (Zug et al. 2001. Herpetology. An Introductory Biology of Amphibians and Reptiles. 2nd ed. Academic Press, San Diego. 630 pp.). Many authors have pointed out that arachnids (mainly Aranae) are one of the most important predators of tadpoles in the Neotropics. Most of these records belong to Pisauridae, Ctenidae, Lycosidae, Sparassidae, and Theraphosidae families (Menin et al. 2005. Phyllomedusa 4:39–47). However, predation on adult and juvenile amphibians has been poorly documented, mainly due to the difficulty of obtaining direct records in the field (Pombal 2007. Rev. Bras. Zool. 24:841–843).

At 2125 h on 9 November 2013, we recorded two predation events of *Hypsiboas pulchellus* juveniles by wolf spiders (Lycosidae). Both observations were made in flooded grasslands of Punta Lara Nature Reserve (34.8043°S, 58.0319°W; WGS84), Buenos Aires, Argentina. In the first case, the predator was an adult male *Lycosa erythrognatha*. It was collected and deposited in the collection of Invertebrate Zoology, La Plata Museum (MLP-Ar 19385). The second predator corresponded to a species belonging to an undescribed genus of the Lycosidae (Fig. 1). This specimen was not collected. During the period we observed both predation events the larval cycle of *H. pulchellus* was concluding (having started in spring) and we noted high densities of juveniles.

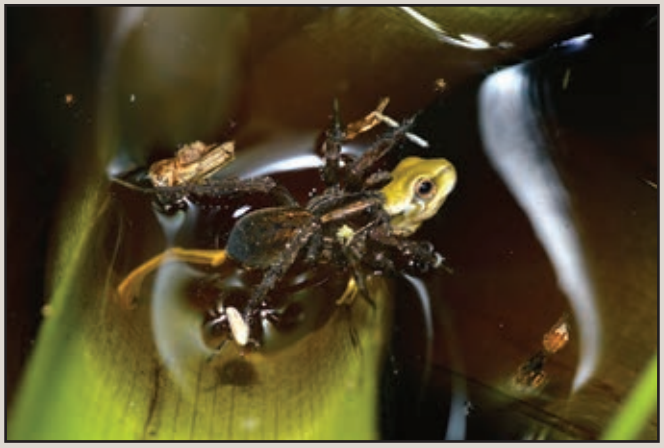

FIG. 1. Undescribed spider of the family Lycosidae (wolf spider) preying on a juvenile *Hypsiboas pulchellus* from Punta Lara Nature Reserve, Argentina.

Spiders are potential predators of both juvenile and adult anurans. Significant linear correlations between the body lengths of prey and predator have been demonstrated, with the size of the spider being similar or slightly smaller than the anuran prey (Menin et al. 2005. Phyllomedusa 4:39–47). The body lengths of *H. pulchellus* span 1.95–5 cm (Maneyro and Carreira 2012. Guía de Anfibios del Uruguay. Ediciones de la Fuga, Montevideo, Uruguay. 207 pp.), whereas the largest wolf spiders can reach more than 30 mm body length (Jocqué and Dippenaar-Schoeman 2015. Spider Families of the World. Royal Museum for Central Africa, Tervuren, Belgium. 336 pp.); therefore, we can infer that these spiders can prey on both juvenile and adult stages of *H. pulchellus*.

Here we present the first records of two species of lycosid spiders preying on *H. pulchellus*. Given that spiders of the Lycosidae are abundant in the Argentine Pampas grasslands (Platnick 2014. www.wsc.nmbe.ch; 15 Jun 2015), they could have an important role in regulating *H. pulchellus* populations.

We thank Jorge Berneche and Jorge Williams for identifying the specimens, and Kini Roesler for editorial suggestions. This study was funded by CREOI, Neotropical Grassland Conservancy and Amphibian Conservation in Agroecosystems Initiative (CoAnA).

***ISCHNOCNEMA GUENTHERI* (Steindachner´s Robber Frog). PREDATION.** *Ischnocnema guentheri* is a litter frog of medium size with crepuscular/nocturnal activity and occasional diurnal activity (Pombal 1997. Rev. Brasil. Biol. 57:583–594; Dixo and Verdade 2006. Biota Neotrop. 6:1–20), especially in rain showers (Giaretta and Facure 2008. Contemp. Herpetol. 3:1–4). It is widespread in the Atlantic forest from southern Brazil to northeastern Argentina (Van Sluys et al. 2010. www.iucnredlist.org; 17 Mar 2015). We report predation upon *I. guentheri* by *Baryphthengus ruficapillus* (Rufous-capped Motmot). Our observation occurred during regular mist-netting (permits: CEMAVE/ICMBio no. 1237, INEA no. 051/2011, SISBIO 14210-7) at Parque Estadual da Ilha Grande (23.1638°S, 44.1888°W, WGS84; 690 m elev.), an oceanic island at Angra dos Reis municipality, Rio de Janeiro State, Brazil. At 0820 h on 16 December 2014 we captured an adult *B. ruficapillus* with a *I. guentheri* (SVL = 31.5 mm; 2.4 g) in its bill. We deposited the frog in Museu Nacional do Rio de Janeiro, Amphibians Collection (MNRJ 88864). During focal observations in October and November 1997 of an active nest of *B. ruficapillus* in the same study area, frogs (unidentified) and reptiles, along with fruits, arthropods, and mollusks, were noted as part of the diet delivered to nestlings (Alves et al. 1999. Ararajuba 7:31–34). Prior published records of predation on frogs by *B. ruficapillus* (Alves et al. 1999, *op. cit.*) and *B. martii* (Rufous Motmot; Master 1999. Wilson Bull. 111:439–440; Alvarado et al. 2013. Herpetol. Rev. 44:298) were all observed during the breeding period. Motmots may prey on frogs over the whole year; however, these events may be easier to detect during the bird's breeding period as adults can be observed carrying prey items to be delivered to the chicks. As *I. guentheri* follows a cryptic strategy (Gomiero et al. 2006. Biota Neotrop. 6:1–5) and is present at low density at Ilha Grande (Rocha et al. 2001. Austral Ecol. 26:14–21) it is possible that *B. ruficapillus* is able to detect this frog moving in the litter during the day. Before our unique predation record of *I. guentheri* by a bird this frog was recorded as an unusual prey of the fish *Brycon opalinus* (Pirapitinga-do-sul), a characid species that regularly consumes fruits and insects (Gomiero et al. 2006, *op. cit.*).

We are grateful to Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) for M.A.S.A (process 308792/2009-2) and UERJ for logistics. We also thank Lulu Stader for the English review, Fundação Carlos Chagas Filho de Amparo à Pesquisa do Estado do Rio de Janeiro (FAPERJ) for the scholarship to C.C.C.M. (process E-26/101.439/2014) and grant to M.A.S.A. (E-26/102837/2012).

***KALOULA PULCHRA* (Banded Bullfrog). DEFENSIVE BEHAVIOR.** At ~1100 h on 12 August 2014 I observed a novel defensive behavior of *Kaloula pulchra* in Bawngkawn, Aizwal, Mizoram, India (23.7554°N, 92.7287°E, WGS84; 1022 m elev.). While I was holding each of the frogs (1 female and 3 males), they puffed up their bodies and released sticky secretions, which are among the recorded defensive behaviors of this species (Sazima 1974. J. Herpetol. 8:376–377). As I continued holding each frog I felt a tingling sensation in my palm and noticed the fourth and largest toe was vibrated by the frog in a very similar way a mouth organ player vibrates his playing hand. This vibration of the toe was followed by a forward body jerk. This continued for as long as I held the frog. Different defensive strategies are used in different phases of predation, and I assume that holding the frog tightly in my hand simulated ingestion. The behavior exhibited by *K. pulchra* is most similar to the "phalanx aggression" reported by Toledo et al. (2011. Ethol. Ecol. Evol. 23:1–25), which is exhibited by some frogs during ingestion. However, as defined by Toledo et al. (2011, *op cit.*), this behavior includes morphological specializations in which the distal phalanges pierce the skin and abrade

the potential predator. Perhaps the vibration of the toe of *K. pulchra* simply produces a tingling sensation in the oral cavity of the predator, and may cause it to loosen the grip on the frog and the subsequent body jerk may set the frog free.

JAYADITYA PURKAYASTHA, Help Earth, Guwahati 781016, Assam, India; e-mail: mail.jayaditya@gmail.com.

***KALOULA WALTERI* (Walter's Narrow-mouthed Frog). PREDATION.** *Kaloula walteri* is a small (SVL = 24.5–35.5 mm) endemic microhylid occurring at sea level to mid-montane rainforest (0–900 m elev.) on Luzon and Polillo Island, Philippines (Diesmos et al. 2002. Copeia 2002[4]:1037–1051). Among invertebrates, crabs are considered important frog predators and several predation incidents of frogs at various life stages by marine and freshwater crabs have been previously documented (Toledo 2005. Herpetol. Rev. 36:395–400; Wells 2007. The Ecology and Behavior of Amphibians. University of Chicago Press, Chicago, Illinois. 1148 pp.; Andrade et al. 2012. Herpetol. Notes 5:173–175; Pyke et al. 2013. Herpetol. Notes 6:195–199; Motta-Tavares et al. 2015. Herpetol. Rev. 46:73–74). Herein, we report an endemic *Sundathelphusa longipes* (Philippine Long-legged Freshwater Crab) eating an adult *K. walteri*.

At 0020 h on 26 March 2015, while conducting fieldwork at Mount Banahao in Barangay Bukal, Municipality of Majayjay, Laguna Province, Luzon Island, Philippines (14.0978°N, 121.482°E, WGS84; 851 m elev.), a freshwater crab (carapace = 23.6 × 19.8 mm) in a small pool with a rocky bottom (ca. 50 × 100 cm; water depth = 8 cm), beside a temporary stream, was observed grasping a deceased and mutilated *K. walteri* (SVL = 34.25 mm) in its claws. The crab immediately released the frog carcass when we approached closer. Upon further inspection, the frog's skin on the body, digits, and internal organs were completely consumed. The frog was identified based on head characteristics, size, and microhabitat. Another adult *K. walteri*, several tadpoles, and three adult crabs were also in the same pool. Although this may be the first reported Philippine frog predation by an invertebrate, it is also possible that the crab only scavenged an already dead frog. The frog (field number EYS 440) and crab (EYS 441) were preserved in 70% ethanol and deposited in the Herpetology Section of the National Museum of the Philippines.

FIG. 1. *Sundathelphusa longipes* with predated *Kaloula walteri*.

***LEPTODACTYLUS FUSCUS* (Whistling Frog). MYIASIS.** Several fly species, from the families Sarcophagidae, Calliphoridae, and Chloropidae, are agents of myiasis and their larvae can develop in living amphibians, often killing their hosts (Crump and Pounds 1985. J. Parasitol. 71:588–591). Myiases have been recorded in anurans including the families Bufonidae, Centrolenidae, Craugastoridae, Dendrobatidae, Hylidae, Leptodactylidae, Odontophrynidae, and Ranidae (Bokermann 1965. Acad. Bras. Cienc. 37:525–537; Gómez-Hoyos et al. 2012. Herpetol. Notes 5:27–29). For leptodactylids, which are conspicuous elements of Neotropical assemblages, there are few available records that report only egg predation by fly larvae on *Leptodactylus bufonius* (Vizcachera White Lipped Frog), *L. fuscus*, and *L. pentadactylus* (South American Bullfrog) (Downie et al. 1995. J. Nat. Hist. 29:993–1003). In this study, we report observations of myiases by two fly species in adult *L. fuscus*, representing the first evidence of myiasis on this species.

Anurans were surveyed at the Pantanal wetlands, in the Nhecolândia region, Brazil (19.6558°S, 57.0417°W, WGS84; 90 m elev.) from 11–19 February 2006. Individuals were caught in pitfall-traps with drift fences. All frogs were inspected for the presence of maggots; infected individuals were placed in plastic jars containing vermiculite, and maggots were allowed to pupate to identify them to species level. The following species of frogs were collected: *Rhinella schneideri* (Cururu Toad; N = 29), *Elachistocleis bicolor* (Two-colored Oval Frog; N = 13), *Pseudis paradoxa* (Paradox Frog; N = 15), *Physalaemus albonotatus* (Menwig Frog; N = 43), *L. chaquensis* (Creole Frog; N = 57), *L. podicipinus* (Pointed-belly Frog; N = 68), and *L. fuscus* (N = 122). *Leptodactylus fuscus* was the only species infected, with five individuals (4.1%) infected (mean intensity = 2.8 maggots per frog). Two fly species, belonging to two families were recovered from *L. fuscus*: *Megaselia scalaris* (Phoridae) and *Oxysarcodexia carvalhoi* (Sarcophagidae). Three (prevalence of 2.5%) of the frogs were infected with *Oxysarcodexia carvalhoi* with 3, 4, 2 maggots/frog, whereas two (prevalence of 1.6%) frogs were infected with *Megaselia scalaris* with 2 and 3 maggots per frog.

Megaselia scalaris is cosmopolitan and synanthropic and larvae are considered extremely opportunistic, with several cases of facultative myiasis reported on a wide variety of hosts, like arthropods (Arredondo-Bernal and Trujillo-Arriaga 1994. Vedalia 1:27), snakes (Silva et al. 1999. J. Med. Entomol. 36:630), and humans (Singh and Rana 1989. J. Med. Entomol. 26:228–229). Considered generalists, *Oxysarcodexia* are known for preferring uninhabited areas (Dias et al. 1984. Mem. Inst. Oswaldo Cruz. 79:83–91) with some cases of facultative myiasis reported in fish, mammals, and carcasses of humans (Mello-Patiu et al. 2014. Rev. Bras. Entomol. 58:142–146). Ecological interaction between flesh eating flies and frogs is an important area of research as previous studies have shown that these relationships are generally lethal (Crump and Pounds 1985, *op. cit.*).

We are grateful to Fundação Cearense de Apoio ao Desenvolvimento Científico e Tecnológico – FUNCAP for a research fellowship to RWA (process BPI-0067-000060100/12) and for a master's fellowship to EPA, and to EarthWatch Institute and Embrapa Pantanal for financial and logistical support.

***LITHOBATES SPHENOCEPHALUS* (Southern Leopard Frog). FALL BREEDING.** For two of the past three years, *Lithobates sphenocephalus* has bred during the fall in Greene Co., Indiana, USA (39.1107°N, 87.2222°W; WGS84). On 16 March 2013, we began capturing overwintered (Gosner stage 25) *L. sphenocephalus* tadpoles in funnel traps set for breeding *L. areolatus* (Crawfish Frog) at three seasonal/semipermanent wetlands. On 13 March 2015, we began capturing overwintered tadpoles at these three wetlands plus three additional wetlands. At four of these wetlands, *L. sphenocephalus* were the only ranid tadpoles present, at the fifth they co-occurred with overwintered *L. catesbeianus* (American Bullfrog) tadpoles, at the sixth they co-occurred with overwintered *L. clamitans* (Green Frog) tadpoles.

McCallum et al. (2004. Southeast. Nat. 3:401–408) offer a detailed account of fall breeding in *L. sphenocephalus* from Arkansas. Minton (2001. Amphibians and Reptiles of Indiana. Indiana Academy of Science, Indianapolis, Indiana. 404 pp.) reports spring breeding and occasional fall calling from Indiana. Our data are the first report confirming fall breeding from Indiana—at a latitude approaching the northern end of this species' range (Lannoo 2005. Amphibian Declines: The Conservation Status of United States Species. University of California Press, Berkeley, California. 1094 pp.)—and based on Minton's experience may represent a new phenomenon at this latitude. Given the documented effects of climate change on accelerating amphibian breeding phenology (Beebee 2002. Conserv. Biol. 16:1454; Blaustein et al. 2002. Conserv. Biol. 16:1454–1455), our observations suggest that in temperate climates, spring breeding phenology may be accelerated through the winter, into the previous fall, under suitable weather conditions (such as heavy rains; McCallum et al. 2004, *op. cit.*).

ROCHELLE M. STILES, Indiana State University, Rm. 135 Holmstedt Hall–ISU, Terre Haute, Indiana, 47809, USA (e-mail: rstiles2@sycamores.indstate.edu); **MICHAEL J. LANNOO**, Indiana University School of Medicine–TH, Rm. 135 Holmstedt Hall–ISU, Terre Haute, Indiana, 47809, USA (e-mail: mlannoo@iupui.edu).

***LITHOBATES SYLVATICUS* (Wood Frog). CANNIBALISM.** It is known that larval *Lithobates sylvaticus* will cannibalize recently oviposited egg masses, newly hatched larvae, and smaller conspecifics (Petranka and Thomas 1995. Anim. Behav. 50:731–739). Although instances of cannibalism of older and more developed conspecifics by younger larvae is known to occur in other anurans (*Scaphiopus hurterii* [Hurter's Spadefoot], *S. bombifrons* [Plains Spadefoot; Bragg 1957. Wassman J. Biol. 15:61–68; Bragg 1964. Herpetologica 20:17–24], *S. multiplicata* [Mexican Spadefoot], *S. couchii* [Couch's Spadefoot; Pomerory 1981. Unpubl. PhD. Dissert. Univ. of California] and *Osteopilus septentrionalis* [Cuban Treefrog; Crump 1986. Copeia 1986:1007–1009]), we were unable to find prior accounts of this phenomenon occurring in *L. sylvaticus*. Here we describe an instance of active cannibalism in *L. sylvaticus* where less developed and presumably younger larvae attacked and devoured an injured and nearly transformed conspecific.

At 2315 h on 16 June 2014 we observed a larval *Ambystoma maculatum* (Spotted Salamander) attacking a larval Wood Frog in an ephemeral wetland (ca. 3.5 m × 2 m and 45 cm deep) at the Smithsonian Environmental Research Center, Anne Arundel Co., Maryland, USA (38.9015°N, 76.5515°W, WGS84; 24 m elev.). The *A. maculatum* larva seized the *L. sylvaticus* larva by its hindquarters and limb and shook it with sideways sweeps of the head. The *L. sylvaticus* larva had fully formed fore and hind limbs, but its tail was not yet resorbed (ca. Gosner stage 42). Shortly after we approached the wetland the *A. maculatum* larva released the *L. sylvaticus* larva, presumably because it was disturbed by our flashlights. Once released, the *L. sylvaticus* larva appeared to be severely injured, and lethargically attempted to swim with irregular and weak lateral undulations. Within ca. 30 sec of its release by the *A. maculatum* larva, the injured *L. sylvaticus* larva was swarmed and consumed by ca. 10 conspecific larvae, only one of which had limbs (hind only; ca. stage 39, the rest appeared to < stage 30). What triggered the swarming behavior and sequence of predatory behaviors of the *L. sylvaticus* cannibals is unclear. It may have been initiated by biochemical cues released by the injured *L. sylvaticus* larvae during the *A. maculatum* attack (Crump 1986. Copeia 1986:1007–1009) and/or by its irregular swimming. Regardless of the specific trigger, it appears as if cannibalism by less developed larvae occurs in *L. sylvaticus* and may be an important component of its reproductive strategy.

TODD A. TUPPER, Biology Department, Northern Virginia Community College, Alexandria, Virginia, 22311, USA (e-mail: ttupper@nvcc.edu); **ROBERT AGUILAR,** Smithsonian Environmental Research Center, Edgewater, Maryland, 21037, USA (e-mail: aguilarr@si.edu).

***LITORIA HAVINA*. PREDATION.** *Litora havina* is a poorly known treefrog recorded from the upper Fly and Kikori Rivers in the southern high rainfall zone of Papua New Guinea, and the Wondiwoi and Fakfak regions of Papua Province, Indonesia (Menzies 2006. The Frogs of New Guinea and the Solomon Islands. Pensoft Publishers, Sofia, Bulgaria. 345 pp.). It occurs in swamps from 300–1300 m above sea level in tropical rainforest, and lays clutches of 10–20 large (ca. 4 mm diam) eggs on vegetation over water (Richards and Günther 2004. The IUCN Red List of Threatened Species. www.iucnredlist.org; accessed 1 Feb 2015). This note presents the first published observation of predation on *L. havina* in the field.

Between 29 June and 27 July 1993 we observed *L. havina* in several swamps around the township of Tabubil, Western Province, Papua New Guinea (5.26°S, 141.22°E, WGS84; 558 m elev.). While looking for frogs at night, we also observed one or more *Tropidonophis* sp. (Keelback Snake) in vegetation around most swamps we visited. On 9 July 1993 we observed a *Tropidonophis* moving among low vegetation in a swamp 13 km S of Tabubil along the Tabubil-Kiunga Road. On that night this swamp hosted a frog chorus containing adult *L. havina* and many tens of their egg masses were found at heights between 0.4 and 2.5 m above water level on the vegetation around the swamp. We saw the snake moving around the swamp over 2–3 h, and collected it just before we left the swamp late in the evening. Upon dissection of the snake we found an adult female *L. havina* and several eggs masses in its stomach (Fig. 1). Although we did not directly observe predation, this confirmed not only our suspicions that *Tropidonophis* were predating adult *L. havina*, but also demonstrated that the snakes were eating the frogs' arboreal egg masses. We are unsure of the specific identity of the snake; four species of *Tropidonophis* (*T. doriae*, *T. mairii*, *T. multiscutellatus*, and *T.*

FIG. 1. An adult female *Litoria havina* (SVL ca. 37 mm) and *L. havina* eggs in the stomach of a *Tropidonophis* sp. (Keelback Snake) from near Tabubil in the Western Province of Papua New Guinea.

statisticus) occur in the general area where our observations were made (O'Shea 1996. A Guide to the Snakes of Papua New Guinea. Independent Publishing, Port Moresby, Papua New Guinea. 239 pp.).

Our field work in Papua New Guinea was done with support from the Ok Tedi Mining Company, and under permits from the Institute of Papua New Guinea Studies and the Papua New Guinea Department of Environment and Conservation.

GREGORY R. JOHNSTON (e-mail: pelecanus85@gmail.com) and **STEPHEN J. RICHARDS**, South Australian Museum, North Terrace, Adelaide, 5000, Australia (e-mail: steve.richards@samuseum.sa.gov.au).

***PHYSALAEMUS PUSTULOSUS* (Túngara Frog). SEXUAL COMMUNICATION.** At ca 1930 h on 14 June 2015 we made an interesting observation of sexual communication of a *Physalaemus pustulosus* in the Darien National Park in Darien (7.747°N, 77.536°W; WGS84), Panama.

Túngara Frogs produce mating calls (ca. 350 ms duration) that consist of a downward frequency sweep which can be produced alone or can be followed by 1–7 short, ca. 45 ms, bursts of sound called "chucks." The call is accompanied by inflation and deflation of a relatively large vocal sac (Ryan 1985. The Túngara Frog, A Study in Sexual Selection and Communication. University of Chicago Press, Chicago, Illinois. 236 pp.). On this night we observed a small group of male Túngara Frogs, ca. 3–6, calling from a puddle on a trail. As chucks are typically always produced immediately after a whine, we were struck by what we thought was a chuck produced in isolation. We then located the male producing the call in question. During ca. 5–10 min of observation, the male did indeed produce calls with only chucks. These chucks sounded similar to chucks typical of this species; although the amplitude seemed a bit lower than typical it was clearly audible. The male also produced whines in isolation and whines followed by chucks as is typical for this species, as well as what is best described as a "half-whine," but he then returned to producing chucks in isolation. During this time we also observed the male inflating and deflating his vocal sac as if he were calling but without any audible call; this occurred several times. In all instances, whether or not accompanied by sound, the inflation-deflation of the vocal sac produced vibrations on the water's surface, which is merely an epiphenomenon of vibrating a structure on the water's surface. During all of these behaviors, chuck-only and half-whine calls, typical whine and whine-chuck calls, and muted vocal sac inflation-deflation, the male was alternating his display with neighboring calling males, as is typical for this species. Thus he was participating in the chorus in a typical manner even when producing an atypical signal.

One of us, MJR, has been studying this species for several decades (Ryan 1980. Science 209:523–525; Ryan 2011. *In* Losos [ed.], In Light of Evolution, Essays from the Laboratory and Field, pp. 185–203. Roberts and Company, Greenwood Village, Colorado) and only once previously did he observe a male producing a chuck-only. Examination of that male's larynx showed it was normal (MJR, unpubl. data; our current permits in the Darien did not allow collecting). Never, to our knowledge, has anyone observed a Túngara Frog inflating and deflating its vocal sac independent of sound production. The diurnal African frog *Phrynobatrachus krefftii* (Krefft's Puddle Frog) also shows this behavior which clearly is a communication signal (Hirschmann and Hödl 2006. Herpetologica 62:18–27). There are similar reports of muted vocal sac inflations for Bornean frogs in the genus *Staurois*, but their role in communication has not been investigated (Boeckle et al. 2009. Herpetologica 65:154–165). This observation is germane to the study of sexual communication in this species for several reasons. Female Túngara Frogs strongly prefer whines with chucks to whines-only (Gridi-Papp et al. 2006. Nature 441:38). Normally, males do not produce chucks without the preceding whine and females do not show phonotaxis to chucks-only. In addition, females do not accurately group whines and chucks to the same source (Ryan 1985, *op. cit.*). A chuck spatially displaced by 135° from a whine is perceptually bound to that whine by the female, (i.e., she perceives the two sounds as a single whine-chuck call), and she then approaches the chuck rather than the whine (Farris et al. 2002. Brain Behav. Evol. 60:181–188). Thus a male producing a chuck-only in a chorus could attract a female if his chuck follows the whine of another male calling within a 135° arc. We knew that; now we know that at least one male in the Darien can produce a chuck without a whine.

Vocal sacs recycle air between the lungs and the vocal sac, saving the male the effort of buccal pumping to fill the lungs between each call (Pauley et al. 2006. Comp. Physiol. Biochem. 79:708–719). In a number of frogs the inflation-deflation cycle of the vocal sac also serves as a visual cue (Starnberger et al. 2014. Anim. Behav. 97:281–288), and as mentioned above in *P. krefftii*, this is true even in the absence of accompanying sound. Our observations show that muted vocal sac inflation-deflation occurs in at least one Túngara Frog in the Darien. In Túngara Frogs the vocal sac inflation synchronous with a call enhances the attraction of the call (Taylor et al. 2008. Anim. Behav. 76:1089–1097), and typically

the vocal sac must be synchronous with the call to produce a salient bimodal display (Taylor et al. 2011. J. Exp. Biol. 214:815–820).

Finally, the movement of the vocal sac also produces water-surface ripples that enhance the saliency of a typical call (Halfwerk et al. 2014. Science 343:413–416). When the deviant male we observed inflated and deflated his vocal sac, not only was he producing a visual cue but vibrational cues as well. Although we have shown that the water-surface vibrations by themselves are not salient as a mating display, they do enhance the acoustic-only component of the male Túngara Frog's display (Halfwerk et al. 2014, *op. cit.)*.

The female Túngara Frog is permissive in responding to and sometimes preferring sexual signals that typically do not exist in nature (Ryan et al. 2010. Curr. Zool. 56:343–357), thus acting on signal variation as it arises. Our observations of this one male Túngara Frog in the Darien rainforest show that there is more standing phenotypic, and perhaps genetic, variation for sexual signaling in this frog than previously appreciated. Thus, we now have evidence of variation arising in both signal production and perception, providing the raw materials necessary for complex anuran signals to evolve.

We thank ANAM for permission to conduct research in the Darien, Sofia Rodriguez for arranging logistics, and Isaac for being an expert guide. We also acknowledge NSF grant IOS 1120031 to MJR, R. Taylor, and R. Page, and the Clark Hubbs Regents Professorship in Zoology to MJR for financial support.

RYAN**, Fine Arts Academy, McCallum High School, Austin, Texas 78756, USA.

***PLECTROHYLA POKOMCHI* (Rio Sananja Spikethumb Frog). ALTITUDINAL DISTRIBUTION.** *Plectrohyla pokomchi* is a critically endangered species of stream-breeding frog endemic to Guatemala. An adult female specimen (SVL = ca. 4 cm) was found climbing on the leaves of a tree fern *Cyathea* sp. (Fig. 1) about 2 m above the ground at 2032 h on 15 March 2014 at Apaj River source within Biotopo Protegido Mario Dary Rivera para la Conservación del Quetzal, Purulha, Guatemala (15.2070°N, 90.2326°W, WGS84; 2120 m elev.). This record extends the upper known vertical distribution from the highest elevation reported of 1900 m by 220 m (Duellman and Campbell 1992. Misc. Publ. Mus. Zool. Univ. Michigan 181:1–32). This species is considered to be declining severely, especially in the location where we found it (Mendelson et al. 2004. Rev. Biol. Trop. 52:991–1000). This record also indicates that, as of 2014, the species is still extant within the confines of the protected area mentioned above. A photographic voucher of the specimen was deposited at Colecciones Biológicas de la Universidad del Valle de Guatemala, Guatemala (UVG-F-0004).

FIG. 1. *Plectrohyla pokomchi* found at 2120 m elev. in Purulha, Guatemala.

We thank Jonathan Campbell for providing comments and exchange of information that improved this note. CECON-USAC and CONAP provided permit # 049-2014 to conduct the research.

DANIEL ARIANO-SÁNCHEZ, Departamento de Biología, Universidad del Valle de Guatemala, Guatemala (e-mail: dariano@uvg.edu.gt); **JOHANNA GIL-ESCOBEDO**, Escuela de Biología, Facultad de Ciencias Químicas y Farmacia, Universidad de San Carlos de Guatemala (e-mail: qbjohana@yahoo.com).

***PRISTIMANTIS CERASINUS* (Clay-colored Rain Frog). MORTALITY.** *Pristimantis cerasinus* is a craugastorid frog found in humid lowland and premontane forests from Nicaragua to Panama (Savage 2002. The Amphibians and Reptiles of Costa Rica. University of Chicago Press, Chicago, Illinois. 934 pp.; Padial et al. 2014. Zootaxa 3825:1–132). At ca. 1100 h on 13 April 2013, an adult *P. cerasinus* was found in the web of a Golden Silk Orbweaver (*Nephila clavipes*, Araneidae) on the Lindero Sur trail at La Selva Biological Station, Costa Rica (10.4300°N, 84.0200°W; WGS 84). We identified the frog as *P. cerasinus* by the presence of heel tubercles, the absence of enlarged supraocular tubercles, the relative width and shape of finger toe pads, the dark brown coloration of the posterior thigh, paired suprascapular ridges shaped as inverted parentheses, and failure of the tip of toe V to reach the ultimate subarticular tubercle on toe IV (Savage 2002, *op. cit.*; Guyer and Donnelly 2005. Amphibians and Reptiles of La Selva, Costa Rica, and the Caribbean Slope: A Comprehensive Guide. University of California Press, Berkeley, California. 299 pp.). Although we did not verify that the frog was depredated by the spider, the frog was dead, its body was desiccated, and strands of spider web were wrapped tightly around the frog's left hind leg at three places.

To our knowledge, this is the first published record of death of a craugastorid frog due to *N. clavipes*. *Pristimantis cerasinus* is known to occupy arboreal perch sites in vegetation at night, and the individual may have jumped from a perch site to be ensnared in the web. *Nephila clavipes* webs are known to entrap hummingbirds (Graham 1997. J. Field Ornithol. 68:98–101), small songbirds (Cox and NeSmith 2007. Florida Field Nat. 35:46–48), and bats (Nyfeller and Knörnschild 2013. PLOS ONE 8:e58120). We are unaware of any records of *N. clavipes* consuming trapped vertebrates, although there are two records of *Nephila plumipes* feeding on unidentified anurans (McCormick and Polis 1982. Biol. Rev. 57:29–58).

We thank Kelsey Reider for verifying the identification of the frog and an anonymous reviewer for suggestions that improved this note. A digital photograph of the frog was vouchered at the Georgia Museum of Natural History (GMNH 50832).

***PSEUDACRIS MACULATA* (Boreal Chorus Frog). CALLING PHENOLOGY.** *Pseudacris maculata* is a widespread hylid found

throughout central North America (Dodd 2013. Frogs of the United States and Canada. Johns Hopkins University Press, Baltimore, Maryland. 982 pp.). Chorus frogs are known to be among the earliest calling species of the season throughout their range. For example, a study analyzing *Pseudacris* breeding call characteristics spanning from Oklahoma to South Dakota began as early as March (Platz 1989. Copeia 1989:704–712). However, occasional calls have been heard in northern Alberta, Canada, extending into late August and mid-September after breeding cessation (Dodd 2013, *op. cit.*), and *P. maculata* call in South Dakota on occasional cool and wet days through the summer (Smith, unpubl. data).

On the early afternoon of 11 October 2014, we heard breeding calls of *P. maculata* in an area about 4.25 km E of Provo, Fall River Co., South Dakota, USA (43.1882°N, 103.7820°W, WGS84; 1100 m elev.). The habitat was a roadside ditch overflow from a semi-permanent wetland. It was 18°C, clear with winds at 5.4 m/sec, and 37% humidity. We classified calling intensity as level II on the Amphibian Calling Index (ACI; Heyer et al. 1994. Measuring and Monitoring Biological Diversity: Standard Methods for Amphibians. Smithsonian Institution Press, Washington D.C. 384 pp.). Later that night, we heard a full chorus (ACI level III) calling from pre-sunset and into the evening on the periphery of a permanent wetland in the ghost town of Ardmore, Fall River Co., South Dakota (43.0214°N, 103.6531°W; 1080 m elev.). The temperature was 16°C, wind at 8.2 m/sec, 54% humidity. Shortly before sunset on 18 October 2014, we located a third site, a cattle pond, where individual *P. maculata* were heard calling (ACI level I). This spot is located approximately 1.3 km E of Smithwick, Fall River Co., South Dakota (43.3038°N, 103.2022°W; 1005 m elev.). It was a clear day at 19°C with 4.9 m/sec winds and 42% humidity. Peak calling season for *P. maculata* within South Dakota is May–July (Dodd 2013, *op. cit.*) and they have been known to call as late as August (Ballinger et al. 2000. Trans. Nebraska Acad. Sci. 26:29–46). *Pseudacris maculata* has not been previously recorded calling later than September (Dodd 2013, *op. cit.*) anywhere in its range.

***PSEUDOPALUDICOLA POCOTO*. PREDATION.** *Pseudopaludicola pocoto* is a newly described small frog species that can be found in open areas within the Caatinga in the states of Paraíba, Rio Grande do Norte, Ceará and Pernambuco in northeast Brazil (Magalhães et al. 2014. Herpetologica 70:77–88). We record a predation event on *P. pocoto* (SVL = 13.83 mm; 3 g) by the spider *Ancylometes rufus* (Fishing Spider; Fig. 1). Our observation took place at the Ecological Station Aiuaba (6.36065°S, 40.07285°W, WGS84; 425 m elev.), municipality of Aiuaba, state of Ceará, Brazil, during the course of an active search of the vicinity of a lake for frogs at 2030 h on 22 January 2015. The individuals were collected, euthanized, fixed in 10% formalin, and preserved in 70% alcohol. Voucher specimens are housed in the Laboratório Especial de Coleções Zoológicas do Instituto Butantan, São Paulo (*A. rufus*, IBSP 166751) and in the Coleção Herpetológica da Universidade Regional do Cariri (*P. pocoto*, URCA-H 10403). Only a few anuran species have been observed being preyed upon by *A. rufus*: *Ischnocnema ramagii* (Paraiba Robber Frog; De-Carvalho et al. 2010. Herpetol. Rev. 41:336–337), *Dendrophryniscus minutus* (Amazonian Tiny Tree Toad), *Dendropsophus minutus* (Lesser Tree Frog), *Hypsiboas geographicus* (Map Tree Frog), *Adenomera*

FIG. 1. Predation of *Pseudopaludicola pocoto* by *Ancylometes rufus*.

andreae (Lowland Tropical Bullfrog; Menin et al. 2005. Phyllomedusa 4:39–47), *Dendropsophus melanargyreus* (Interior Tree Frog; Azevedo 2011. Biota Neotrop. 11:349–351), *Dendropsophus sarayacuensis* (Shreve's Sarayacu Tree Frog; Rodrigues and Arruda 2007. Herpetol. Rev. 38:437), and *Scinax alter* (Crubixa Snouted Tree Frog; Prado and Borgo 2003. Herpetol. Rev. 34:238–239). The record presented here increases our knowledge of the relationship between spiders and anurans, highlighting the existence of important trophic connections between these groups. This is the first predation event registered for *P. pocoto*.

We thank Fundação Cearense de Apoio ao Desenvolvimento Científico e Tecnológico (FUNCAP) for a research fellowship to RWA (process BPI-0067-000060100/12) and for a Masters fellowship to EPA, Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) for a Masters fellowship to CFS and TFQ, and PhD fellowship to LAFS, and the researchers at the Butantan Institute, Antônio Domingos Brescovit and Paulo André Margonari Goldoni for their contributions.

***RANA TEMPORARIA* (Common Frog). MAXIMUM SIZE.** Maximum body size reported for *Rana temporaria* in the literature is 100 mm (Bannikov et al. 1977. A Guide to Amphibians and Reptiles of the USSR. Moscow, Prosveshchenie. 415 pp.; Gollmann et al. 2014. *In* Böhme [ed.], Handbuch der Reptilien und Amphibien Europas. Bd 5/III A: Froschlurche (Anura) III A (Ranidae I), pp. 305–437. AULA-Verlag, Wiebelsheim). On 28 September 2012, we found an adult female *R. temporaria* on the forest road near Sekowiec, Bieszczadzki National Park, Poland, in the San River valley (49.2360°N, 22.5637°E; WGS84). The frog was 110.1 mm SVL, representing a new maximum size for the species. This exceeds the maximum recorded SVL for the species by 10.1%. According to Gollman et al. (2014, *op. cit.*), *R. temporaria* reaches maximum body size in northern Europe along the transect of

FIG. 1. Maximum size *Rana temporaria* from Sekowiec, Bieszczadzki National Park, Poland. Coin size = 18.5 mm.

65°N. Our observation demonstrates that maximum sized frogs can be found not only in the north.

KONSTANTIN D. MILTO (e-mail: coluber@zin.ru) and **OLGA S. BEZMAN-MOSEYKO**, Zoological Institute, Department of Herpetology, St. Petersburg, Universitetskaya emb., 1, 199034, Russia.

***RHACOPHORUS PARDALIS* (Harlequin Tree Frog). DEFENSIVE BEHAVIOR.** Defensive behavior of anuran amphibians was thoroughly reviewed in Toledo et al. (2011. Ethol. Ecol. Evol. 23:1–25), who recognized about 30 types of such behavior. Eye-protection has been described in a number of species (Toledo et al. 2011, *op. cit.*) and here we report this defensive behavior for *Rhacophorus pardalis*. Observations were made in the lowland mixed-dipterocarp rainforest near the Kuala Belalong Field Studies Centre in Ulu Temburong National Park (Brunei Darussalam; 4.546°N, 115.157°E, WGS84; 119 m elev.) at 2230 h on 5 February 2015. An adult male individual (SVL = 52.4 mm) was captured on understory vegetation (ca. 1.8 m above the forest floor) during a night survey. When attempting to capture the individual, the frog pressed its body to the ground, slightly arched its back and raised its forelimbs to its head. In this position the webbed front limbs completely covered its eyes and it displayed its red and yellow coloration almost completely (Fig. 1). The eyes were open and the individual remained in this position for at least 2 min. During subsequent handling the back remained arched and it stayed motionless. No defensive call or smell was emitted. This behavior was observed in one of the five individuals handled during this field survey. This type of defensive behavior has also been reported from two other treefrogs in the genus, *Rhacophorus feae* (Thao Whipping Frog; Duong and Rowley 2010. Herpetol. Rev. 41:342; Vinh et al. 2013. Herpetol. Rev. 44:129) and *Rhacophorus margaritifer* (Java Flying Frog; Streicher et al. 2011. Herpetol. Rev. 42:590).

FIG. 1. *Rhacophorus pardalis* displaying defensive behavior.

We are grateful for financial support received (OPVK-CZ.1.07/2.2.00/28.0149).

***RHINELLA* GR. *MARGARITIFERA* (Mitred Toad). PREDATION.** *Rhinella* gr. *margaritifera* are a species complex of medium-sized toads that inhabit forest litter, occurring throughout Amazonian South America to eastern Panama (Frost 2015. http://research.amnh.org/vz/herpetology/amphibia; 9 Apr 2015). *Rhinella marina* is native from south Texas in the United States to southern Brazil (Lever 2001. The Cane Toad. The History and Ecology of a Successful Colonist. Westbury Publishing, Otley, West Yorkshire. 230 pp.). During a field expedition to the Serra Azul in western Pará state, city Monte Alegre, Brazil (1.1787°S, 54.1868°W; WGS84)

FIG. 1. Adult male *Rhinella marina* preying upon *Rhinella* gr. *margaritifera*.

FIG. 2. *Rhinella* gr. *margaritifera* released from the mouth of the adult male of *Rhinella marina*.

we observed an adult male *R. marina* swallowing a live adult *R.* gr. *margaritifera* near a weir at 2000 h on 13 January 2015 (Fig. 1). The *R. marina* started ingesting the toad headfirst leaving only the legs of *R.* gr. *margaritifera* out of the mouth (Fig. 1). We captured the *R. marina* and removed *R.* gr. *margaritifera* for the purpose of photographing it and identifying it (Fig. 2). We then released both individuals. *Rhinella marina* is considered a generalist and opportunistic predator that includes both invertebrates and vertebrates in its diet (Lever 2001, *op. cit.*).

RAUL DE PAULA DA SILVA FRÓIS (e-mail: raul.p.s.frois@gmail.com), **JOYCE CELERINO DE CARVALHO** (e-mail: joyce.celerino@gmail.com), **EMIL JOSÉ HERNÁNDEZ-RUZ**, Laboratório de Zoologia, Faculdade de Ciências Biológicas, Universidade Federal do Pará, Campus de Altamira, Rua Coronel José Porfírio, 2515 - CEP 68.372-040 - Altamira – PA, Brazil (e-mail: emilhjh@yahoo.com).

***RHINELLA MARINA* (Cane Toad). REPRODUCTIVE ACTIVITY.** Amplexus in most anuran species lasts for a relatively short duration of a few hours to days (Wells 1977. Anim. Behav. 25:666–693, but see Dole and Durant 1974. Copeia 1974:230–235). The potential costs of amplexus include metabolic costs (McLister 2003. Can. J. Zool. 81:388–395), increased predation risk (Howard 1981. Ecology 62:303–310), decreased locomotor (sprint and swim) performance, and a reduction or loss of feeding opportunities (Bowcock et al. 2009. Copeia 2009:29–36). In laboratory experiments, feeding rates of amplexed female *Rhinella marina* were reduced and males did not feed at all (Bowcock et al. 2009, *op. cit.*). These laboratory results suggest that there may be significant costs involved in prolonged amplexus for both males and females. Toads may remain in amplexus overnight since egg deposition often doesn't begin until the following morning (Floyd 1983. Unpubl. PhD thesis. Griffith University, Australia. 315 pp.). However, amplexus over a period of days has not been reported under natural conditions (Bowcock et al. 2009, *op. cit.*).

Here we report prolonged amplexus of at least 14 days in a pair of *R. marina* in Paramaribo, Republic of Suriname (5.8288°N, 55.1436°W; WGS84). The amplexed pair (Fig. 1) was first observed at approximately 0830 h on 11 June 2014 and observed in amplexus on 10 different days between 0730–0900 h through 24 June 2014. They were still amplexed when observers left Suriname on 24 June 2014. All observations took place from an outdoor dining area approximately 2.5 m from a bird feeder stocked with bread and fruit which spilled to the ground where the amplexed pair and one other toad were periodically observed (Fig. 1). Although *R. marina* are considered to be primarily nocturnal, a lone female was photographed eating bread at 0845 h on 6 June 2014. Diurnal feeding and consumption of stationary anthropogenic food items (e.g., carrot peelings, corn kernels, black-eyed peas, and canned dog food) has been previously observed in *R. marina* (Alexander 1964. Herpetologica 20:255–259). Identification of the pair was achieved by comparing images taken of the pair over the duration and matching unique markings on the female between days (e.g., small white spot on the first tubercle posterior to male foreleg on the right lateral side; Fig. 1). In addition to the pair, no more than one other toad was observed at the same time. These observations demonstrate that prolonged amplexus in *R. marina* occurs under natural conditions. Although no measurements of male mass were taken, the male's concave sides, visible in the image taken on 17 June 2014 (Fig. 1), suggest that the male was not feeding. While not definitive, these observations lend credence to the laboratory results of Bowcock et al. (2009, *op. cit.*), that males do not feed while amplexed with females and males may be more negatively energetically impacted by prolonged amplexus than females, when the female has access to food.

FIG. 1. Amplexed pair of *Rhinella marina* surrounded by pieces of bread in Paramaribo, Suriname.

We thank Paul Ouboter and Rawien Jairam, University of Suriname, for their hospitality and support during our visit. Tom Mathies and an anonymous reviewer provided comments on a draft of this manuscript. Funding was provided by a National Science Foundation HBCU-UP (USA) grant to C. d'Orgeix.

***SCAPHIOPUS HURTERII* (Hurter's Spadefoot). ENDOPARASITES.** We report, for the first time, on endoparasites from *Scaphiopus hurterii* from Louisiana. On 3 April 2012, we collected six adult *S. hurterii* (5 males, mean SVL = 66.8 mm, range 62.0–70.0 mm and 1 female, SVL = 68.0 mm) by hand from northern Louisiana (3.75 km NE Spearsville, Union Parish, Louisiana, USA; 32.9562°N, 92.5718°W, WGS84) and examined them for helminth parasites. *Scaphiopus hurterii* were euthanized with a concentrated chloretone solution and their gastrointestinal tract, from the esophagus to rectum, was removed and split entirely, placed in a Petri dish containing amphibian saline (0.6% NaCl) and examined under a dissection microscope; we removed their lungs, gonads, and other visceral organs as well. Cestodes were stained with acetocarmine and mounted in Canada Balsam, and nematodes and acanthocephalans were studied as temporary mounts in glycerol. Voucher specimens of *S. hurterii* are deposited in the Arkansas State University Museum of Zoology (ASUMZ) Herpetological Collection, State University, Arkansas, and helminths are deposited in the Harold W. Manter Laboratory of Parasitology (HWML), University of Nebraska-Lincoln.

Five of six *S. hurterii* were infected with at least one helminth. Two of six had the cestode *Mesocestoides* sp. encapsulated within gastrointestinal tissues. Five of six were infected with the nematode *Oswaldocruzia pipiens*. One of six was infected with numerous nematodes, *Cosmocercoides variabilis*, in the rectum. One of six was infected with an unidentified oligacanthorhynchid acanthocephalan cystacanth; in this case, *S. hurterii* is likely a paratenic (transport) host. Amphibians are known as paratenic hosts of species of the acanthocephalan family

Oligacanthorhyncidae (Schmidt 1985. *In* Crompton and Nickol [eds.], Biology of the Acanthocephala, pp. 273–305. Cambridge University Press, Cambridge, UK). Development to the adult worm occurs when the amphibian is eaten by a suitable definitive host.

One female was infected with both *Mesocestoides* sp. and *O. pipiens* and one male (SVL = 70.0 mm) was infected with all four parasite species. Both *Mesocestoides* and *O. pipiens* have been reported in *Anolis carolinensis* (Green Anole) from Louisiana (Conn and Etges 1984. Proc. Helminthol. Soc. Washington 51:367–369) and in *S. hurterii* from Oklahoma previously (McAllister et al. 2005. Texas J. Sci. 57:383–389). *Cosmocercoides variabilis* has been reported from *Gastrophyrne carolinensis* (Eastern Narrowmouth Toad) from Louisiana (McAllister and Bursey 2005. Comp. Parasitol. 72:124–128) and from *S. hurterii* in Oklahoma (McAllister et al. 2005, *op. cit.*).

In summary, the acanthocephalan cystacanth represents a new paratenic host record for *S. hurterii* (HWML 64768), although not a new geographic record for the parasite in Louisiana (Elkins and Nickol 1983. J. Parasitol. 69:951–956). We suggest that additional *S. hurterii* from other parts of Louisiana be examined as new host and distributional records may be added to the growing list of helminths of this amphibian.

We thank S. E. Trauth (ASUMZ) and S. Gardner (HWML) for expert curatorial assistance. The Louisiana Department of Wildlife and Fisheries issued a scientific collecting permit to MBC.

BURSEY**, Biology Department, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu).

***SCAPHIOPUS HURTERII* (Hurter's Spadefoot). REPRODUCTION.** *Scaphiopus hurterii* is considered an explosive breeder associated with torrential rainfall. Because of these requirements, they are seldom observed breeding. Between 11 March and 3 April 2012, we observed this species breeding three times during torrential rainfall events at a site in extreme northern Louisiana (3.8 km NE Spearsville, Union Parish, Louisiana, USA; 32.9562°N; 92.5718°W, WGS 84). On 11 March (ambient temperature 16.1°C), we discovered a breeding site (Fig. 1A), consisting of a temporary pool in a cattle pasture and were able to capture a total of eight toads (five males, three females). On 21 March (ambient temperature 12.2°C), we were able to document another breeding event at the same site and were able to capture 11 individuals (nine males, two females). Finally, on 03 April (ambient temperature 15.5°C), we observed another breeding event and were able to capture six individuals (five males, one female). The mean snout-vent length (SVL) for a small sample of adult individuals was 63.2 mm (range 57–68 mm) for six females and 67.4 mm (range 62–71 mm) for nine males. Our male-biased captures are likely the result of our sampling time (ca. 2200–2400 h), since males migrate to breeding site first and start calling to attract females. Both calling males and amplectant pairs were observed during all three of these events. Previously, the lowest air temperature for calling males in Louisiana was 16°C (Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge, Louisiana. 300 pp.); however, rainfall more so than ambient temperature is likely a predictor of breeding. We also collected six egg clusters that were laid on vegetation (Fig. 1B) and mean egg counts were 100.8 (range 49–131). This is comparable to mean egg cluster counts of 111.8 in Arkansas (Trauth and Holt 1993. Bull. Chicago Herpetol. Soc. 28:236–239). Voucher specimens were deposited within the Arkansas State University Museum of Zoology (ASUMZ) Herpetology Collection, State University, Arkansas as ASUMZ 32017–32025.

***TELMATOBIUS ATACAMENSIS* (Atacama Water Frog). CANNIBALISM.** Among anurans, cannibalism has been documented both in tadpoles preying on conspecific eggs or tadpoles and in adults preying on those stages and/or on other postmetamorphic individuals (Polis and Myers 1985. J. Herpetol. 19:99–107). *Telmatobius atacamensis* is a medium-sized aquatic frog living in high altitude streams of a restricted area of the Puna Plateau of Salta Province, in northern Argentina (Lavilla and Barrionuevo 2005. Monogr. Herpetol. 7:115–165). As in most of the 62 species of *Telmatobius*, the diet of *T. atacamensis* is unknown, although some data exist for nine species (e.g., Lavilla 1984. Acta Zool. Lilloana 38:51–57; Wiens 1993. Occ. Pap. Mus. Nat. Hist. Univ. Kansas 162:1–76; Formas et al. 2005. Monogr. Herpetol. 7:103–114).

On 24 February 2005 a female *T. atacamensis* (SVL = 60.4 mm) was found in a small lateral pool (ca. 200 × 300 cm, 50 cm deep) that had lost contact temporarily with the stream Los Patos (24.3108°S, 66.2162°W, WGS84; 3945 m elev.), close to San Antonio de Los Cobres. The female was fixed 12 h after collection (FML SB0157). Upon examination of the female's stomach contents, a juvenile of the same species (SVL ca. 28 mm) was found. It was only partially digested at the anterior part of the head and therefore was perfectly recognizable. In the same pool, four adult *T. atacamensis* were found and many tadpoles and juveniles were observed.

This is the first case of cannibalism in *T. atacamensis*. Cannibalism has been recorded among species of *Telmatobius* so far only in *T. culeus* (Pérez Bejar 1998. Unpubl. dissertation Universidad de San Andres, Bolivia). Among the species of Ceratophryidae, a phylogenetically related group, cannibalism is common both in adults and larvae (Schalk et al. 2014. South. Am. J. Herpetol. 9:90–105). Cannibalism in aquatic environments has been associated with high concentrations of several cohorts in small bodies of water, a condition observed in our study site.

J. SEBASTIÁN BARRIONUEVO, Museo Argentino de Ciencias Naturales "Bernardino Rivadavia" Buenos Aires, Argentina; e-mail: sbarrionuevo@macn.gov.ar.

***THELODERMA ASPERUM* (Hill Garden Bug-eyed Frog). DEFENSIVE BEHAVIOR.** Amphibians exhibit a wide range of defensive behaviors that differ between taxonomic groups (Toledo et al. 2011. Ethol. Ecol. Evol. 23:1–25). Herein, we report the antipredator behavior of a southeast Asian rhacophorid frog, *Theloderma asperum*. This genus currently includes 23 recognized species (Frost 2014. http://research.amnh.org/vz/herpetology/amphibia/; 31 Mar 2015). *Theloderma asperum* inhabits lowland to mountain forests from northeast India through Myanmar and adjacent China, upland Thailand, Laos, central and northern Vietnam to southwest Guangxi and south Indonesia (Sumatra).

At 2308 h on 27 June 2012, we captured an adult female *T. asperum* (SVL = 30 mm) on vegetation (ca. 2 m above the forest floor) near Sa Pa town in mountainous subtropical forest of Hoang Lien Mountains, northern Vietnam (22.328°N, 103.826°E, WGS84; 1266 m elev.). After its capture, the individual was put on the ground where it immediately curled up into an arched and rigid posture. The head was ventrally flexed, all limbs were bent and kept close to the body (Fig. 1). Eyes were closed the whole time and the individual remained in this position for at least 15 min (Fig. 1A) and remained arched and motionless during subsequent handling (Fig. 1B). No defensive call or smell was emitted.

We consider the defensive behavior shown in this case as "shrinking or contracting behavior" (sensu Toledo et al. 2010. J. Nat. Hist. 44:1979–1988; Toledo et al. 2011, *op. cit.*), a type of death feigning (or thanatosis) behavior. There is a published technical report that gives a similar description of this behavior in *T. asperum* (see Pawar and Birand 2001. A Survey of Amphibians, Reptiles, and Birds in Northeast India. Centre for Ecological Research and Conservation, Mysore, India. 120 pp.). The genus *Theloderma* is well known for cryptic coloration and body shape (e.g., Vitt and Caldwell 2014. Herpetology: An Introductory Biology of Amphibians and Reptiles. 4th ed., Elsevier, San Diego, California; Rauhaus et al. 2012. Asian J. Conserv. Biol. 1:51–66), which are types of passive defense employed by anurans (Toledo et al. 2011, *op. cit.*). For example, *T. asperum* is a tree bark and potentially a bird-dropping mimic and *T. corticale* (Mossy Frog) is mottled green and brown and resembles moss growing on rock

FIG. 1. Defensive behavior displayed by *Theloderma asperum* in northern Vietnam. A) Dorsal view, B) ventral view.

(Vitt and Caldwell 2014, *op. cit.*). Therefore, they may use contracting behavior in addition to cryptic coloration to evade predation. A similar case of defensive behavior has been reported for another member of the family Rhacophoridae, *Rhacophorus feae* (Fea's Treefrog; Vinh et al. 2013. Herpetol. Rev. 44:129).

DANIEL JABLONSKI, Department of Zoology, Comenius University in Bratislava, Mlynská dolina B-1, 842 15, Bratislava, Slovakia (e-mail: daniel.jablonski@balcanica.cz); **DAVID HEGNER**, Mšenská 3938/26, 466 04 Jablonec nad Nisou, Czech Republic.

***ZACHAENUS CARVALHOI* (Carvalho's Bug-eyed Frog). DIET.** Frogs in the genus *Zachaenus* (Cycloramphidae) are associated with leaf litter in forested areas and are endemic to the Atlantic Forest of Brazil (Izecksohn 1982. Arq. Univ. Fed. Rural. R. de Janeiro 5:7–11). The information on diet for this genus is exclusive to *Z. parvulus* (Van Sluys et al. 2001. J. Herpetol. 35:322–325). Herein we present data on the diet of specimens of *Z. carvalhoi* present in the collections of the Universidade Federal de Juiz de Fora (UFJF 663, 674–678, 692, 708, 753, 760, 773, 781, 792–800, 819–830, 863–865) collected at three forest fragments in the municipality of Juiz de Fora, state of Minas Gerais, Brazil: Fazenda Floresta (21.7425°S, 43.2922°W; WGS84), Reserva Biológica Municipal Poço D'Anta (21.7541°S, 43.3108°W), and Parque Municipal da Lajinha (21.7922°S, 23.3808°W). We found identifiable items in 17 out of the 36 guts examined. The items were identified to the lowest possible taxonomic level. The primary items found were Coleoptera (76%) and Hymenoptera (ants; 58%), and occasional items were Myriapoda (11%), Arachnida

(Pseudoscorpionida; 11%), Hemiptera (Cercopidae 5%), Isoptera (5%), and Mollusca (Gastropoda, 5%). We also found plant matter in two individuals (11%).

The variety of prey items found in *Z. carvalhoi* indicates a generalist diet. These suggestions are consistent with data on the diet of other members in the family, with Hymenoptera and Coleoptera being the most common food items (e.g., Van Sluys et al. 2001, *op. cit*; Siqueira et al. 2006. J. Herpetol. 40:520–525; Maia-Carneiro et al. 2012. Zoologia 29:277–279). The presence of Hymenoptera and Myriapoda in the diet of *Z. carvalhoi* is noteworthy, as individuals in these groups produce toxins that potentially could be biosequestrated or transformed into skin chemicals (Hantak et al. 2013. J. Chem. Ecol. 39:1400–1406). The species in Cycloramphidae are not known to possess skin toxins, but do have macroglands (lateral glands in *Thoropa*, inguinal macroglands in *Cycloramphus*, and inguinal gland conglomerates in *Zachaenus*; Verdade 2005. Unpublished thesis, Universidade de São Paulo, Brazil), whose function and secretions have not been studied.

We thank FAPESP (processes 2003/10335-8, 2006/01266-0), FAPEMIG (process 2008/08853-4), and CNPq for financial support; Ibama/ICMBio for collection permits (SISBIO 14555-2, SISBIO 15363-1, and SISBIO 26157-3). We thank Celso Henrique Varela Rios for help in the field and Carolina Yamaguchi for help in identifying stomach contents.

TESTUDINES — TURTLES

***CHELYDRA SERPENTINA* (Snapping Turtle). DIET AND FORAGING BEHAVIOR.** *Chelydra serpentina* are omnivorous, consuming an extensive variety of foods including worms, mollusks, arthropods, and other invertebrates, fish, birds, amphibians, small mammals, small turtles, snakes, and other vertebrates, algae, aquatic macrophytes, and the fruits, stems, and leaves of higher plants (Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed. Johns Hopkins University Press, Baltimore, Maryland. 827 pp.). On 14 May 2015 at 1310 h, I observed a large (carapace length ca. 40.0 cm) *C. serpentina* browsing on Skunk Cabbage (*Symplocarpus foetidus*) on land at a distance of ~2 m from the shoreline of a large pond in Espy, Columbia Co., Pennsylvania, USA (41.010206°N, 76.416294°W, WGS84; elev. ~150 m). The *C. serpentina* was observed for approximately 5 minutes at a distance of ~8 m. During observation, the *C. serpentina* removed Skunk Cabbage leaves by shearing the stalk near the base of each plant and subsequently consumed each leaf. When approached for closer observation, the *C. serpentina* became aware of my presence, ceased feeding, and assumed a defensive posture before retreating into the water. Closer inspection of the area in which this observation occurred revealed that approximately 40–50% of stems among ~20 clusters of Skunk Cabbage plants were sheared in a similar manner to those consumed by the observed *C. serpentina* (Fig. 1). Several partial fragments of Skunk Cabbage leaves were also noted on the surrounding substrate.

FIG. 1. Skunk Cabbage (*Symplocarpus foetidus*) stalks browsed by *Chelydra serpentina*.

Multiple markings in the substrate surrounding Skunk Cabbage clusters consistent with *C. serpentina* claw marks and a "slide" depression on the shoreline on which the individual *C. sperpentina* traveled upon during retreat may suggest that either the same or multiple individuals frequent this area to feed upon Skunk Cabbage. I noted an additional area that displayed similar characteristics (browsed Skunk Cabbage and multiple *C. serpentina* claw markings) along the pond shoreline approximately 20 m from the first.

Chelydra serpentina occasionally browse vegetation on land. Ernst and Lovich (2009, *op. cit.*) report an observation of two large individuals on land browsing upon sedge grass. However, Skunk Cabbage appears to be an uncommon component of *C. serpentina* diet. Upon examination of the stomach contents of 470 *C. serpentina*, Alexander (1943. J. Wildl. Manage. 7:278–282) reported Skunk Cabbage in less than 1% of individuals studied. Observations reported herein suggest that terrestrial browsing of Skunk Cabbage by *C. serpentina* may be more typical in this species than previously documented. The pond shore and surrounding area in which these observations occurred is a portion of a once larger wetlands area that has been reduced and fragmented by development. Alternatively, *C. serpentina* may more commonly utilize Skunk Cabbage as a food source when other resources are limited.

I thank Amber L. Pitt for advice during the preparation of this note. Observations reported herein were conducted during turtle transect survey research approved by Bloomsburg University of Pennsylvania IACUC (Protocol #131, Summer 2015). Additional photographs of Skunk Cabbage browsed by *C. serpentina* and other aspects of the area described in this note are available from the author.

SEAN M. HARTZELL, Department of Biological and Allied Health Sciences, Bloomsburg University of Pennsylvania, Bloomsburg, Pennsylvania 17815, USA; e-mail: smh14844@huskies.bloomu.edu

***GOPHERUS AGASSIZII* (Agassiz's Desert Tortoise). ATTEMPTED PREDATION.** Desert Tortoises have many predators (Rostal et al. 2014. Biology and Conservation of North American Tortoises. Johns Hopkins University Press, Baltimore, Maryland. 190 pp.). Several ophidian species have been identified as potential predators (Ernst and Lovich 2009. Turtles of the United States and Canada. Johns Hopkins University Press, Baltimore,

FIG. 1. *Arizona elegans* attempting to prey on *Gopherus agassizii* at Edwards Air Force Base, Kern Co., California, USA.

Maryland. 827 pp.), but no published reports have mentioned *Arizona elegans* (Glossy Snake).

At 0827 h on 3 October 2013, we observed an *Arizona elegans* ca. 80 cm total length attempting to prey on an 8.6-yr old juvenile *Gopherus agassizii* (midline carapace length = 90.5 mm, width = 72.4 mm, height = 42.1 mm, weight = 137.3 g) that had been fitted with a radio-transmitter and released the previous day from a head-start facility at Edwards Air Force Base in the Mojave Desert, Kern Co., California, USA. When first observed, the tortoise was 2 cm outside the entrance of a rodent burrow, the snake was between the tortoise and burrow entrance, and the snake had the head of the tortoise firmly in its jaws. The tortoise initially was immobile and probably cold (air temperature at 1 cm 18.0°C, soil temperature 16.2°C). The snake coiled around the tortoise shell three times and pulled the tortoise head first, closer to, and partially within the burrow entrance. The snake appeared to use the radio transmitter attached to the 5th vertebral scute of the tortoise as purchase for its coils. The tortoise with the snake coiled around it was too large to be pulled further into the burrow, and the head and anterior half of the tortoise were not visible (Fig. 1). The right hind foot of the tortoise was pinned backwards by the snake's coils and was immobile. The snake appeared to squeeze the tortoise shell with its coils; at the same time, the snake's head was still out of view within the burrow and possibly still gripping the tortoise's head. At 0912 h, the tortoise and snake moved slightly, and the snake's head, with partially opened mouthed and disarticulated jaws, came into view, exiting the burrow along the bridge of the tortoise shell. One of the coils loosened. Both animals remained still for another 10 min. Observations ceased and were re-initiated at 1110 h, but neither the tortoise nor the snake was evident at the burrow. The tortoise had moved 20 m away and was basking at the entrance of a small mammal burrow. No injuries were apparent on head or limbs. After a few minutes, the tortoise walked into the burrow and turned sideways, almost entirely within the burrow. By 1345 h, the tortoise was 15 cm into the burrow tunnel and no longer visible. The tortoise dug the burrow deeper and did not emerge again until 10–11 October, when it moved to and enlarged another rodent burrow for fall-winter brumation. The juvenile tortoise had apparently been too large for the snake to eat and was still alive the following spring. Our observation is the first record of an *A. elegans* attempting to prey on a juvenile *G. agassizii*. The diet of *A. elegans*, based on evaluation of 205 museum specimens, is composed of lizards, birds, mammals, and insects (Rodríguez-Robles et al. 1999. J. Herpetol. 33:87–92). The diet differed significantly by snout–vent length, with larger snakes consuming birds, followed in descending order by mammals, and lizards. If *A. elegans* had attempted to prey on a recently hatched, soft-shelled juvenile tortoise, the predation likely would have been successful.

ASHLEY SPENCELEY, JEREMY MACK (e-mail: jmack@usgs.gov), and **KRISTIN H. BERRY**, U.S. Geological Survey, Western Ecological Research Center, Riverside, California 92518, USA (e-mail: kristin_berry@usgs.gov).

***GOPHERUS AGASSIZII* (Agassiz's Desert Tortoise). MECHANICAL INJURY.** On 3 June 2015 at 1024 h, a team of U.S. Geological Survey scientists located an immature *Gopherus agassizii* at Joshua Tree National Park, near the southern Cottonwood Canyon entrance, that had been injured by a large *Ferocactus cylindraceus* (California Barrel Cactus) spine. The *G. agassizii* was estimated to be four years old by counting growth rings on the plastron, and was 89.4 mm in carapace length and weighed 160 g. It was found basking on a flat spot on a north-facing, steep, rocky slope with the *F. cylindraceus* spine impaling it under the right leg. The area is typical of the Sonoran Desert in California, with several species of cacti, some of which are locally abundant.

The tip of the spine had entered the body at the right anterior axillary area and penetrated the lower body to the posterior portion of the neck, at a right angle to the long axis of the *G. agassizii*, along a plane parallel with the ground, and close to the inside of the plastron. The spine was removed; significant tissue debris had formed around the diameter of the spine for approximately a centimeter from the insertion spot. It is unknown how long the spine had been in the *G. agassizii* but the dark color of the spine

FIG. 1. Immature *Gopherus agassizii* with *Ferocactus cylindraceus* spine that was removed from its body. Built-up tissue can be seen on the removed spine from the left end to where it overlaps the seam between the second and third vertebral scutes of the *G. agassizii*.

suggests that either it had been present for a relatively long time or that the spine was from an already dead cactus. The length of the inserted portion of the spine was about 27 mm, and the total length was about 63 mm (Fig. 1). The average diameter of the spine was about 1.5 mm. The protruding portion of the spine had likely inhibited movement of the immature tortoise.

Lanius excubitor (Northern Shrike) has been known to impale hatchling *Testudo gracea gracea* (Moorish Tortoise) on spiny plants in Morocco (Barje et al. 2005. Amphibia-Reptilia 26[1]:113–115). We do not believe local shrikes (*Lanius ludovicianus*) are the cause of this event. The mean carapace length of *T. gracea gracea* reported in the study above was 28 mm, which is smaller than the mean carapace length of a *G. agassizii* hatchling at 40–50 mm (Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed. Johns Hopkins University Press, Baltimore, Maryland. 827 pp.). *Lanius ludovicianus* in the southwestern United States weigh an average of 40 g and select prey weighing an average of 8 g (Bartholomew et al. 1953. Physiol Zool. 162–166; Slack 1975. Auk 812–814). Even if the event occurred in the *G. agassizii*'s first year, *G. agassizii* hatchlings are much bigger than *T. gracea gracea*, rendering *L. ludovicianus* an unlikely predator due to their small size (Barje et al 2005, *op. cit.*).

We do not know how this injury occurred but present three possibilities. First, it is possible the *G. agassizii* was feeding near a cactus or on a cactus flower and became impaled. However, *F. cylindraceus* is not listed specifically in *G. agassizii* diets (Grover and DeFalco 1995. Desert Tortoise (*Gopherus agassizii*): Status-of-Knowledge Outline with References. USDA For. Serv. Gen. Tech. Rep. Int-GTR-316). Given the rocky and steep terrain, a second possibility is that the *G. agassizii* may have fallen into a living or dead cactus. Third, it is also possible that an avian predator like a *Corvus corax* (Common Raven) may have picked up the tortoise and dropped it by chance on a *F. cylindraceus* (Boarman 2003. Environ Manage. 32:205–217). Mechanical injuries from other plant parts have been reported in *G. agassizii* (Medica 2007. Herpetol Rev. 38: 446–448). As cacti are prominent in the Sonoran Desert, this may happen to *G. agassizii* with some regularity. However, we are unaware of any previous reports of *G. agassizii* being impaled by large cactus spines.

Research was supported by a Local Assistance Grant to JEL from the California Department of Fish and Wildlife to the Coachella Valley Conservation Commission. Research was conducted under permits from the U.S. Fish and Wildlife Service, the National Park Service, and the California Department of Fish and Wildlife. We thank Michele Phillips for her help on this project. Geoff McGinnis of the University of California, Riverside Center for Conservation Biology and the Friends of the Desert Mountains provided us with assistance in the field. Allan Muth of the Boyd Deep Canyon Desert Research Center of the University of California, Riverside provided accommodations and stimulating discussions during our research. Any use of trade, product, or firm names is for descriptive purposes only and does not imply endorsement by the U.S. Government.

***KINOSTERNON HIRTIPES* (Rough-footed Mud Turtle). AERIAL BASKING, WINTER ACTIVITY, HABITAT, AND NEW LOCALITY.** *Kinosternon hirtipes* occurs from extreme western Texas, south into northern and central Mexico (Ernst and Lovich 2009. Turtles of the United States and Canada. 2nd ed. Johns Hopkins University Press, Baltimore, Maryland. 827 pp.). In Texas, *K. hirtipes* is restricted to the Alamito Creek drainage in Presidio Co. (Scudday and Miller 1986. The Status of the Chihuahuan Mud Turtle, *Kinosternon hirtipes murrayi*. Report to United States Fish and Wildlife Service, Washington, D.C. 40 pp.), and classified as a threatened species owing to its limited distribution and continuing habitat degradation (Texas Parks and Wildlife Department. 2013. Species of Conservation Concern. Available from: www.tpwd.state.tx.us). *Kinosternon hirtipes* is one of the least-studied turtles in North America and very little is known concerning its natural history (Ernst and Lovich, *op. cit.*; Lovich and Ennen 2013. Amphibia-Reptila 34:11–23). We here present observations of aerial basking by *K. hirtipes* made during late winter at a locality in Presidio Co., Texas, USA, describe the habitat at this site, and comment on the significance of our findings.

On 14 February 2009 (1400–1555 h), one of us (LM) observed two adult (straight-line carapace length ca. 140–160 mm) *K. hirtipes* basking in direct sunlight on exposed rocks in springfed pools about 50 m apart on the floor of Robbers Roost Canyon (30.0451°N, 103.9425°W; 1294–1304 m elev.). Both turtles were basking within 30 cm of the water; one on a horizontal surface and the other on a steep incline (ca. 40°). The carapace of one turtle was covered with a thick growth of algae. The carapace of the second turtle lacked algae and appeared dry, suggesting this individual had been basking > 30 minutes. We estimated the air and water temperature in Robbers Roost Canyon at the time the turtles were basking to be 18°C and 15°C, respectively. The minimum and maximum air temperature recorded at the nearest weather station (Marfa, Texas) on 14 February 2009 was -3.3°C and 18.8°C, respectively. Air temperature on the preceding day had likewise been relatively mild (range = 3.8–20°C) (Available from: www.wunderground.com). Small cyprinids (possibly Red Shiner [*Cyprinella lutrensis*]), sunfish (*Lepomis* spp.), and largemouth bass (*Micropterus* spp.) were also present in the pools, the latter being potential predators of neonate *K. hirtipes* (Smith et al. 2015. Herpetol. Rev. 46:82–83).

The pools in Robbers Roost Canyon are up to 8 m wide in places, 3–4 m deep, relatively clear, and contain dense mats of muskgrass (*Chara* sp.) and filamentous algae. Narrow channels link the pools, which extend along the canyon floor for about 2 km before debouching into an arroyo leading southwest to Alamito Creek, a distance of approximately 6.0 km. Neither the arroyo nor Alamito Creek contain water except after heavy rainfall (Wilde and Platt 2011. J. Big Bend Studies 23:85–106). Robbers Roost Canyon appeared relatively undisturbed at the time of this observation; evidence of cattle grazing was minimal and woody riparian vegetation remained largely intact. There are no obvious habitat linkages between Robbers Roost Canyon and other wetlands in the Alamito Creek watershed known to harbor *K. hirtipes*, the nearest of which is 20 km SW (straight-line distance) at Plata (Scudday and Miller, *op. cit.*). The intervening xeric landscape may function to isolate the *K. hirtipes* population at Robbers Roost Canyon.

Our observation of basking *K. hirtipes* in Robbers Roost Canyon is noteworthy for several reasons. First, to our knowledge this is the first report of aerial basking by *K. hirtipes*. A juvenile *K. hirtipes* that appears to be basking on a horizontal tree branch is pictured in Ernst and Lovich (*op. cit.*), although no details are provided in the accompanying figure caption or text. Aerial basking by *K. hirtipes* is not unexpected as this behavior is reportedly commonplace among North American Kinosternidae

(*Kinosternon arizonense*, *K. flavescens*, *K. sonoriense*, *K. subrubrum*, *Sternotherus carinatus*, *S. depressus*, *S. minor*, *S. odoratus*; reviewed by Ernst and Lovich, *op. cit.*). Our observation seems clearly related to thermoregulation given the turtles were basking in direct sunlight in early to mid- afternoon on a warm late winter day. Second, our observation constitutes the first report of winter activity in a natural population of *K. hirtipes*. Beltz (1954. Herpetologica 10:124) described an adult female that escaped from captivity and overwintered beneath a pile of leafy debris in southern California, but otherwise winter activity of *K. hirtipes* has gone unreported. Our observation lends support to an earlier suggestion by Iverson et al. (1991. J. Herpetol. 25:64–72) that *K. hirtipes* is probably sporadically active throughout the winter on warm days.

Robbers Roost Canyon also represents a new locality record for *K. hirtipes* in Texas where it was previously known from only six small wetlands in the Alamito Creek drainage (Scudday and Miller, *op. cit.*). At one time connectivity between these populations was probably maintained by Alamito Creek, a permanent free-flowing stream corridor linked by tributary creeks to riparian wetlands and springs throughout its drainage (Wilde and Platt, *op. cit.*). These wetlands later became isolated after Alamito Creek ceased flowing (except following heavy rainfall) due to hydrological changes wrought by over-grazing and water diversion in the late 1800s (Wilde and Platt, *op. cit.*). Without stream corridors to provide connectivity between occupied sites, the continued exchange of individuals among the remaining populations can seemingly be accomplished only by lengthy (> 5 km) overland movements across an arid landscape. Successful overland dispersal seems doubtful given the high rate of evaporative water loss reported for *K. hirtipes* and its inability to tolerate prolonged dehydration (Seidel and Reynolds 1980. Comp. Biochem. Physiol. 67A:593–598; Ligon and Peterson 2002. Physiol. Biochem. Zool. 75:283–293); however, further study is required to resolve this question of obvious conservation significance.

Finally, our observation compliments the few previously published descriptions of *K. hirtipes* habitat. Iverson et al. (*op. cit.*) reported a large population of *K. hirtipes* inhabiting a springfed stream flowing through arid grassland in Chihuahua, Mexico. The stream was described as clear and fast-flowing, 100–200 cm wide (average width = 100 cm) and 10–100 cm deep (average depth = 50 cm) with a sand-gravel substrate and deeply undercut banks where turtles sought refuge. Dense stands of *Typha* were established along the bank in backwater areas where the current was reduced. In another area of Chihuahua, Van Devender and Lowe (1977. J. Herpetol. 11:41–50) stated *K. hirtipes* is "very common in streams." Ernst and Lovich (*op. cit.*) described a population of *K. hirtipes* inhabiting a livestock pond in Texas (480 m^2 and 4.0 m deep) "choked" with muskgrass (*Chara* sp.). Smith et al. (*op. cit.*) captured a record-sized *K. hirtipes* in a springfed wetland that had been dammed to form a livestock watering pond. The pond was clear, averaged 5.0 m deep with a relatively stable water level even during drought conditions, and supported abundant emergent aquatic vegetation (*Scirpus*, *Typha*, and Poaceae), mats of *Chara* sp., and filamentous algae. Taken together, our observation and reports of others suggest that permanent streams and springfed wetlands with an abundance of submerged and emergent aquatic vegetation provide habitat for *K. hirtipes*. Such habitats are probably crucial for the survival of *K. hirtipes* in west Texas (Ernst and Lovich, *op. cit.*; Smith et al., *op. cit.*).

Fieldwork was conducted under a Scientific Research permit (SPR-0307-844) issued by the Texas Parks and Wildlife Department to SGP with the approval of the Sul Ross State University (SRSU) Institutional Animal Care and Use Committee. The Hardrock Mining Company and Jake and Martha McCandles are thanked for allowing us to conduct research on their properties. Support for this project was provided by Research Enhancement Grants from SRSU to SGP.

PLATT, Department of Biology, Box C-64, Sul Ross State University, Alpine, Texas 79832, USA (current address: Wildlife Conservation Society - Myanmar Program, Office Block C-1, Aye Yeik Mon 1st Street, Hlaing Township, Yangon, Myanmar; e-mail: sgplatt@gmail.com); **LEWIS MEDLOCK**, 407 South Third Street, Alpine, Texas 79831, USA (e-mail: medlock.lewis@yahoo.com).

***MACROCHELYS APALACHICOLAE* (Apalachicola Alligator Snapping Turtle). AERIAL BASKING.** The Alligator Snapping Turtle was recently split into three species (Thomas et al. 2014. Zootaxa 3786:141–165). Observations of basking *Macrochelys* are rare. Carr et al. (2011. IRCF Reptiles & Amphibians 18:2–5) reviewed nine previously documented basking events and Elsey and Bourgeois (2014. Herpetol. Rev. 45:688–689) recently reported two additional observations. With the exception of Thomas (2009. Herpetol. Rev. 40:336), who reported on *M. suwanniensis* in the Suwannee River, Florida (*M. temminckii* at time of observation), all previously reported aerial basking observations were of *M. temminckii*. Here we report the first two aerial basking observations for the newly recognized *M. apalachicolae*.

On 13 May 2014 at 1603 h, EPH and JDM observed an immature *M. apalachicolae* (estimated mass less than 4.5 kg) basking on the Choctawhatchee River, Holmes Co., Florida, USA. The turtle was perched on a willow trunk (*Salix* sp.) that was horizontal to the river surface (Fig. 1). The turtle was located 2 m out from the bank and approximately 0.5 m above the water. The turtle escaped into the water after a photo was taken. Air temperature was approximately 32°C under partly sunny skies.

A second immature *M. apalachicolae* (similar in size to the above) was observed basking by JDM at 1547 h on 21 May 2014 on the Apalachicola River, Liberty Co., Florida, USA. This turtle was perched more than 1 m above the water's surface at the top of a nearly vertical snag located 5m out from the bank. The turtle was clinging to the snag with the head up, but upon detection it dropped into the river. Air temperature was approximately 32°C under mostly sunny skies.

FIG. 1. An immature *Macrochelys apalachicolae* basking along the Choctawhatchee River, Holmes Co., Florida, USA.

***MALACLEMYS TERRAPIN RHIZOPHORARUM* (Mangrove Diamond-backed Terrapin). DIET.** *Malaclemys terrapin rhizophorarum,* one of seven subspecies of *M. terrapin,* inhabits subtropical mangrove habitats in South Florida, USA. In temperate climates *M. terrapin* is largely carnivorous, feeding primarily on gastropods, bivalves, and decapod crustaceans (Tucker et. al. 1995. Herpetologica 51:167–181; Butler et. al. 2012. Chelon. Conserv. Biol. 11:124–128). In addition to its preferred prey, *M. t. rhizophorarum* has also been reported to consume barnacles, fish, and vegetation (Tucker et. al. 1995, *op. cit.*; Butler et. al. 2012, *op. cit.*; Tulipani 2013. Ph.D. Dissertation. The College of William and Mary, Williamsburg, Virginia. 224 pp.). Herein, we report observations regarding the diet of *M. t. rhizophorarum* from the southernmost extent of their range in the Florida Keys, USA.

On 9 April 2013, we collected opportunistic fecal samples from 29 adult female *M. t. rhizophorarum* with straight plastron lengths (SPL) ranging from 145–175 mm (mean 158 mm ± 7) and one yearling *M.t. rhizophorarum* (SPL 30 mm), from Barracouta Key (24.54799°N, 81.92127°W; WGS84) 12 miles W of Key West, Florida, USA. We identified 14 different categories of fecal remains, ten of which were classified as food (Table 1), with an additional four classified as non-food (e.g., Ostracoda [ostracods], parasites, sand/sediment, and other). The "other" category consisted of small bits of glass and an unidentifiable substance. *Cerithidea scalariformis* (Ladder Horn Snail) was the primary food item occurring in 100% of samples and accounted for approximately 97% of total dry mass for each mature terrapin as well as across all samples. Vegetation, unidentifiable gastropod and bivalve remains, *Melampus coffeus* (Coffee Bean Snail), crabs, and small fish constituted the remaining 3% of samples by weight. Gastropod opercula were documented in 93% of the samples, and although not identified to species, were frequently associated with the shell fragments of *C. scalariformis*. Crab remains were too fragmented for species identification but likely were *Uca* sp. (Fiddler Crab) based their small size and their common occurrence along the edge of the island. Insects were identified in 77% of the samples, but this food item may be over-represented because of difficulty distinguishing between prey and incidental drowning after terrapins were placed in collection buckets. Parasites were found in 48% of the samples examined, including the one yearling terrapin.

The one yearling terrapin's fecal sample contained the remains of four food (insect, crab, *C. scalariformis*, vegetation) and three non-food items (parasites, sand, Ostracoda). Diets were similar between the two age groups with all items (food and non-food) documented in the yearling's fecal sample also documented in mature terrapins, but in different proportions. Unlike the mature adults, insects dominated the yearling's sample in both abundance and mass, with few crab or Ladder Horn Snail remains. Intriguingly, unlike adult female diet samples, the one yearling sample was dominated by beetle and other insect remains that were clearly ingested as prey and may be an important food item for smaller size classes. This could be due to their using habitats around dead wood, or their smaller head size may preclude them from producing the crushing jaw forces necessary to process harder-shelled prey.

All sampled mature *M. t. rhizophorarum* were females, captured on the interior of the island during the end of the dry season. During the time of this study, *C. scalariformis* dominated the habitat while crabs and bivalves were found less frequently and concentrated along the edge of the island. This pattern of prey availability could explain the appearance of selective feeding on *C. scalariformis*, since these were more abundant and less mobile than crabs. Further investigation into the diet of *M. t. rhizophorarum* is desirable, including samples from males and females in different seasons, to provide valuable information on the foraging ecology of terrapins living in the southernmost extreme of their range.

This study was supported by the United States Geological Survey, the United States Fish and Wildlife Service (Permit # 2013-007), and funded through the USGS Priority Ecosystem Science Program. We thank B. Smith, A. Daniels, and S. Sisk for assistance in collecting terrapins and fecal samples, and the Ford family for providing a location to process the terrapins. We also thank S. Kudman for help processing samples in the lab, and M. Cherkiss and J. McClain Counts for suggestions and comments that improved the manuscript. Any use of trade, product, or firm names are for descriptive purposes only and do not imply endorsement by the U.S. Government.

***PELOMEDUSA GALEATA* (South African Helmeted Turtle). MUTUALISTIC BEHAVIOR.** There are few published instances of turtles showing mutualistic behavior by removing ectoparasites from other organisms. In Ontario, Canada, *Chrysemys picta* (Painted Turtle) were observed removing leeches from *Chelydra serpentina* (Snapping Turtle), and this was judged to be the first documentation of active participation in any mutualism by any species of turtle (Krawchuk et al. 1997. Can. Field Nat. 111:315–317). This type of interaction was recorded between *C. picta* and *C. serpentina* ten times, and the *C. serpentina* remained passive during these interactions. In South Africa, *Pelomedusa subrufa* were observed to remove ticks from *Diceros bicornis* (Black Rhinoceros) on several occasions, and the *D. bicornis* did not interfere with the turtles' activities (Deane 1969. Lammergeyer 2:69, Rochat 1969. Lammergeyer 2:69). These observations did not report a specific locality in South Africa, and may refer to either *P. subrufa* sensu stricto or *P. galeata*, following a recent taxonomic revision (Petzold et al. 2014. Zootaxa 3795:523–548).

FIG. 1. *Pelomedusa galeata* inspecting the head of an adult male *Phacochoerus africanus* (Warthog).

FIG. 2. *Pelomedusa galeata* removing and eating a *Tabanus biguttatus* from the warthog.

FIG. 3. *Pelomedusa galeata* climbing onto the back of the *Phacochoerus africanus* to remove a tick. The *P. africanus* remained motionless throughout this encounter.

We observed a lone adult male Warthog (*Phacochoerus africanus*) southeast of Hilltop Camp in the Hluhluwe section of the Hluhluwe-iMfolozi Park, KwaZulu-Natal, South Africa on 4 February 2015 at 1255 h. The *P. africanus* approached and then walked into a small roadside wallow; we observed it from 10 m away, while remaining inside our vehicle. As soon as the *P. africanus* entered the water, it was approached by two adult *Pelomedusa galeata*, and as it lowered itself into the water, the turtles began swimming around the warthog's body. The warthog stopped moving once the water level had reached its neck, with only the shoulders and the top of the back and rump above water. The turtles inspected the skin of the warthog and occasionally lunged forward at unseen items. The turtles' claws were frequently seen touching the warthog's skin as they swam around it, and they closely inspected the face and snout of the warthog with no adverse response (Fig. 1). The warthog's back had a Hippo Fly (Tabanidae: *Tabanus biguttatus*) attached to it, and after 5 min of observation, the warthog lowered itself further into the water. As soon as the fly was in reach of one of the turtles, it reached up onto the warthog's back and ate the fly (Fig. 2). The turtle then climbed onto the back and bit something on the warthog (Fig. 3). Upon review of our photographs, we were able to see at least ten ticks embedded in the left side of the warthog's body, and one tick was clearly the object that the turtle is biting in Fig. 3. Other than adjusting its body depth in the water, the warthog remained motionless throughout the observation time (approximately 10 min).

This is the first documentation of a mutualism between *Phacochoerus africanus* and *Pelomedusa galeata*. Taken together with published information on *P. subrufa/galeata* and *D. bicornis* in mud wallows, we expect that additional field observation will show that ectoparasite removal is an opportunistic mutualism by *Pelomedusa* spp. This behavior should be looked for in mud wallows during the dry season throughout the range of this genus, and the mammalian partners in this mutualism could include other common species that use these wallows (e.g., *Syncerus caffer* [African Buffalo], *Connochaetes taurinus* [Blue Wildebeest], and *Loxodonta africana* [African Elephant]).

ANDREW W. JONES (e-mail: ajones@cmnh.org), and **MICHELLE LEIGHTY JONES**, Cleveland Museum of Natural History, 1 Wade Oval Drive – University Circle, Cleveland, Ohio 44106, USA.

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle). DEFENSIVE BEHAVIOR.** *Sternotherus odoratus* is a small, freshwater turtle in which aerial basking is generally uncommon; however, this species will occasionally bask on logs, within tree limbs, and along shorelines (Nickerson 2000. Herpetol. Rev. 31:238–239; Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed. Johns Hopkins Univ. Press, Baltimore, Maryland. 827 pp.). When disturbed, basking adult *S. odoratus* commonly escape by retreat into the water, while juveniles latch onto logs or tree limbs, presumably to impede removal (Ernst and Lovich 2009, *op. cit.*). On 21 June 2015 at 1220 h, I observed an adult *S. odoratus* basking

FIG. 1. Defensive posture of an adult *Sternotherus odoratus*.

along the shoreline of a small, unnamed pond within the Montour Preserve, Montour Co., Pennsylvania, USA (41.096794°N, 76.663693°W; WGS84). Instead of retreating into the water, when approached the *S. odoratus* retracted its head, tucked its limbs slightly underneath its plastron and tightly grasped the grassy substrate along the shoreline (Fig. 1). The behavior observed by the adult *S. odoratus* appears to be analogous to the grasping behavior described in juveniles by Ernst and Lovich (2009, *op. cit.*). This observation suggests that the defensive behavior employed by *S. odoratus* juveniles may be retained by adults in some populations. Furthermore, this note may represent the first account of this behavior occurring upon non-woody (i.e., logs, tree limbs) substrate.

Many thanks to Amber L. Pitt for identifying the *S. odoratus*, and to Michael B. Hartzell and Sarah C. Hartzell for transportation to the Montour Preserve.

SEAN M. HARTZELL, Department of Biological and Allied Health Sciences, Bloomsburg University of Pennsylvania, Bloomsburg, Pennsylvania 17815, USA; e-mail: smh14844@huskies.bloomu.edu.

CROCODYLIA — CROCODILIANS

***ALLIGATOR MISSISSIPPIENSIS* (American Alligator). TELEMETRY UNIT RETENTION.** Numerous radio-telemetry studies have been conducted on American Alligators in Louisiana (Joanen and McNease 1970. Proc. SE Assoc. Game Fish Comm. 24:175–193; Joanen and McNease 1972. Proc. SE Assoc. Game Fish Comm. 26:252–275) and Florida (Rosenblatt et al. 2013. Estuarine, Coastal, and Gulf Sci. 135:182–190). Many telemetry studies are only able to collect data from animals for less than one year (see review in Rosenblatt, *op. cit.*). We herein report on the recovery of a surgically implanted telemetry unit in an American Alligator after over 13 years.

As part of a study on thermoregulation in alligators (Seebacher et al. 2003. Physiol. Biochem. Zool. 76:348–359) conducted in June–July 2001 (summer) and February 2002 (winter), 20 free-ranging alligators were implanted with temperature loggers, and seven of the alligators were also implanted with a temperature-sensitive radio transmitter in each season (Seebacher et al., *op. cit.*). The study was conducted on Rockefeller Wildlife Refuge in Grand Chenier, Louisiana, USA (29.7167°N, 92.8167°W), a coastal marsh habitat. The transmitters and data loggers were surgically implanted into the peritoneal cavity via a small incision in the right flank of each alligator, as previously described (Seebacher et al., *op. cit.*). After the alligators were released to the wild, we recovered seven alligators in both the summer phase and the winter phase; obtaining continuous body temperature data for up to 17 days in summer and up to 13 days in winter for the short-term study (Seebacher et al., *op. cit.*).

On 3 September 2014, during the annual nuisance alligator harvest conducted on Rockefeller Refuge, one of the study animals from the summer 2001 phase was recaptured. During the lengthy time period since the initial capture and study, the identifying foot/web tag was lost. However, when the alligator was butchered at a processing shed, the radio transmitter spontaneously fell out of the peritoneal cavity and was recovered. Employees of the facility brought this to the attention of SFD, who inquired with RME and PLT as to the origin of the unit. The identifying number on the transmitter was from an alligator that was captured on 22 June 2001 and was released on 24 June 2001 after surgical implantation of the data logger and radio transmitter. The female alligator was initially 1.78 m total length and had a mass of 16.8 kg at capture in 2001. The exact length at recapture in 2014 was unknown, as the skin (with identifying CITES tag) had been separated from the carcass from which meat was being deboned when the transmitter was noted. However, six female alligators caught that day on Rockefeller Refuge with the same identifying tail notch as the marked study alligators ranged in length from 2.03–2.39 m total length. The number of days elapsed between release and recapture was 4821 days (13 years, 2 months, and 12 days).

It is noteworthy that this recovery was made after such a long time interval after implantation. The transmitter fell out of the abdominal cavity during processing; there was apparently no evidence of adhesions or complications from the earlier procedure; the alligator appeared healthy and robust. The transmitter appeared nearly pristine and the identifying numbers were clearly visible and no wear or erosions were seen on the protective coating on the unit. Of the seven alligators recovered with data loggers in the initial summer phase in July 2001, four also had telemetry transmitters; thus the unit recovered in 2014 was one of only three possibly remaining from the summer experimental phase conducted over 13 years earlier. It is also significant that the alligator had such long term survival, particularly after the region was adversely impacted by two major hurricanes (Hurricane Rita in 2005 [Lance et al. 2010. J. Exp. Zool. 313A:106–113], and Hurricane Ike in 2008). In some cases flooding from hurricanes pushed alligators north off the refuge, and alligators can disperse long distances (Lance et al. 2011. SENA 10:389–398), although we documented several cases of nest-site fidelity by nesting females on Rockefeller Refuge, even after Hurricane Rita and a subsequent catastrophic drought (Elsey et al. 2008. SENA 7:737–743).

We thank the staff at D & D in Gueydan, Louisiana for assistance in recovery of the telemetry transmitter.

Sydney, School of Biological Sciences, Heydon Laurence Building, Sydney, New South Wales 2006, Australia.

***CROCODYLUS ACUTUS* (American Crocodile). ECTOPARASITISM.** Crocodilians host a diversity of parasites (Tellez 2013. A Checklist of Host-Parasite Interactions of the Order Crocodylia. University of California Press, Berkeley, California. 388 pp.). Although parasitism of crocodilians by endoparasites and aquatic ectoparasites is fairly well-documented (Cott 1961. Trans. Zool. Soc. Lond. 29:211–359; Webb and Manolis, 1983. Aust. Wildl. Res. 10:407–420; Riley and Huchzermeyer 2000. Copeia 2000:582–586), comparatively little is known regarding parasitism of crocodilians by terrestrial ectoparasites. Scattered reports exist describing crocodilian parasitism by ticks (Terenius et al. 2000. J. Med. Entomol. 37:973–976; Rainwater et al. 2001. J. Wildl. Dis. 37:836–839; Sejas, 2007. Interciencia 32:56–60), and even fewer reports exist regarding parasitism of crocodilians by hematophagous (blood-feeding) flies, although due to their affinity for aquatic habitats crocodilians are generally more vulnerable to the latter.

Hematophagous fly parasitism has been reported for *Crocodylus niloticus* (Nile Crocodile) (Hoare 1931. Parasitology 23:449–484; Cott, *op. cit.*) as well as multiple caiman species including *Caiman crocodilus* (Spectacled Caiman), *Melanosuchus niger* (Black Caiman), *Paleosuchus trigonatus* (Smooth-fronted Caiman), and *P. palpebrosus* (Dwarf Caiman) (Medem 1981. Cespedesia 10:123–191; Henriques et al. 2000. Rev. Brasil. Zool. 17:609–613; Ferreira et al. 2002. Mem. Inst. Oswaldo Cruz, Rio de Janeiro. 97:133–136). However, to our knowledge no published accounts exist regarding hematophagous fly parasitism in New World crocodiles. Here, we report an observation of parasitism by a hematophagous fly on *C. acutus* in Costa Rica.

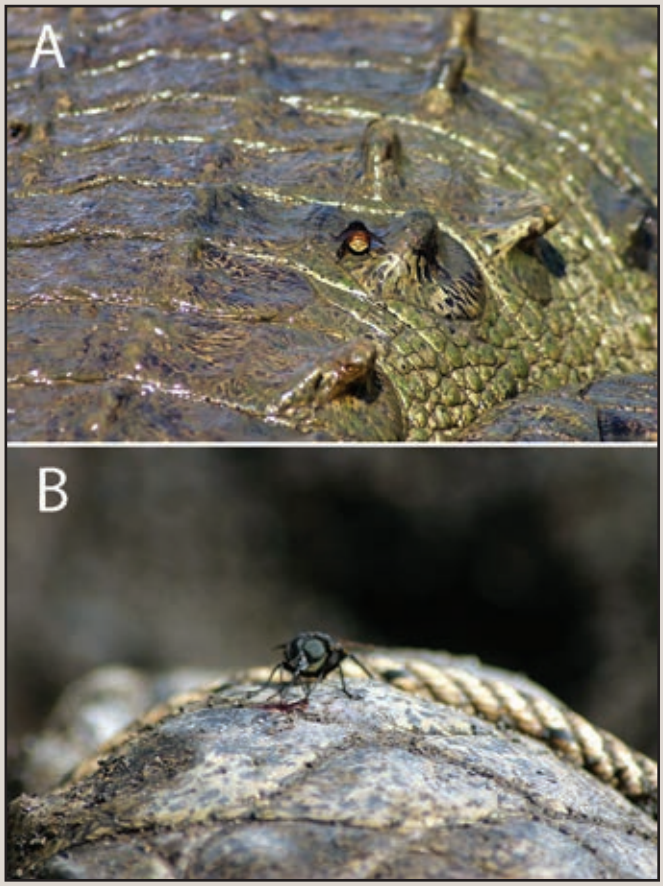

FIG. 1. A) *Fidena bicolor* (rear view) on the back of *Crocodylus acutus* in the Tarcoles River, Costa Rica. B) *Fidena bicolor* (front view) on the rear leg of *Crocodylus acutus* in the Tarcoles River, Costa Rica. Note the tip of the fly's proboscis inserted into the skin between scales.

On 12 September 2007 at approximately 1530 h, we captured an adult (total length = 376 cm) male *Crocodylus acutus* in the lower Tarcoles River, Costa Rica (9.785892°N, 84.617481°W; WGS84) during a study of ocular disease in this crocodile population (Rainwater et al. 2011 J. Wildl. Dis. 47:415–426). The crocodile was captured by actively attracting it to bait on the river bank and then placing a breakaway snare around its upper jaw. Prior to capture, as the crocodile slowly crawled onto the bank toward the bait, we observed a *Fidena bicolor* (horse fly; Diptera: Tabanidae) hovering around the crocodile and eventually landing on its back (Fig. 1A). Following capture and during our examination of the animal, we observed a *F. bicolor* (possibly the same one) on the crocodile's right leg. The fly appeared to be feeding, as the tip of its proboscis was inserted between two scales on the leg (Fig. 2B) (Medem, *op. cit.*). The fly remained in the same position for approximately 10 sec and then flew away, possibly disturbed by our constant movement around the crocodile.

Although the horse fly *Fidena flavipennis* is known to feed on caiman in Costa Rica (John Burger, pers. comm.), to our knowledge this is the first report of ectoparasitism by a hematophagus fly on a New World crocodile and by *F. bicolor* on any crocodilian.

Voucher photographs of *Fidena bicolor* were deposited in the Campbell Museum, Clemson University (CUSC 2912). We thank John Burger for identifying the horse flies and Stanlee Miller for archiving the voucher photographs.

Box 596, Georgetown, South Carolina 29442, USA (e-mail: trrainwater@gmail.com); **JUAN RAFAEL BOLAÑOS MONTERO**, Asociación de Especialistas en Crocodílidos, 200m Oeste y 150m Sur del Templo Católico, Heredia, Costa Rica; **BRADY R. BARR**, National Geographic Channel, 1145 17th Street NW, Washington, D.C. 20036, USA; **STEVEN G. PLATT**, Wildlife Conservation Society, Myanmar Program, Office Block C-1, Aye Yeik Mon 1st Street, Hlaing Township, Yangon, Myanmar.

***CROCODYLUS ACUTUS* (American Crocodile). ECTOPARASITE.** Crocodilians are host to a diverse assemblage of parasite species, particularly endoparasites (Tellez 2013. A Checklist of Host-Parasite Interactions of the Order Crocodylia. University of Press, Berkeley, California. 388 pp.; Tellez and Nifong 2014. Intl. J. Parasitol: Parasitol. Wild. 3:227–235). Ectoparasitism, however, is not a common phenomenon. The thick epidermal layer, in addition to osteoderms, likely decreases the success rate of penetration or attachment of ectoparasites onto the crocodile. Thus, unlike the majority of other vertebrates, the crocodilian epidermis is perhaps the primary defense mechanism against ectoparasitism. Previous records of ectoparasitism, or micropredation, have documented penetration or attachment of ectoparasites between scale sutures and softer locations of the skin, such as on the legs, and around the border of the eyes and nose (Tellez 2013, *op. cit.*). Parasitic arthropods represent the largest group of ectoparasites to infect crocodiles, which include members from the order Diptera, Hemiptera, Ixodida, Porocephalida, and Sessilia (Tellez 2013, *op. cit.*). Here, we report the collection of an isopod (Phylum Arthropoda: Order Isopoda) from a wild crocodile in Belize, in concomitance to recording the first documentation of isopod parasitism among crocodilians.

FIG. 1. *Crocodylus acutus* (American Crocodile) with parasitic isopod *Rocinela signata* on the eye.

On 26 August 2013, during a routine evening tagging survey, a female, sub-adult (total length = 115.40 cm) *Crocodylus acutus* was captured by hand for the first time and microchipped (#0A02153718) at 2015 h. The crocodile was located via spotlight under a home on stilts in the cove at the lagoon-side entrance to San Mateo, Ambergris Caye (17.933283°N, 87.9566694°W) in which the salinity of the water was measured at 31 ppt via a portable refractometer. The crocodile was only in fair condition in conjunction with a slightly sunken supertemporal fossae and relatively underweight. Approximately five isopods were randomly attached to the crocodile's nictating membrane of the left eye, as well as attached to the ear flaps. While the isopods were being removed from the eye, the importance of documenting the infection became apparent, as this was the second observation of isopods infecting *C. acutus* since July 2013. As such, photos were taken of the remaining isopod (Fig. 1). Upon returning from the crocodile survey, the isopod was placed in a small vial and preserved in alcohol until further taxonomic identification. Since this event, several additional *C. acutus* have been recorded with isopod infections of the eyes and ear flaps.

The isopod was identified as *Rocinela signata* from the family Aegidae, a common micro-predator and/or parasite of marine fish (Cavalcanti et al. 2012. Mar. Biol. Rec. 5:66–70). To our knowledge, this is the first record of *R. signata* infecting a marine-inhabiting reptile. It is likely that our findings are an example of accidental parasitism, or an anomaly of micro-predation on crocodiles. However, the decline of fish hosts around Ambergris Caye due to overfishing, pollution, and habitat destruction of fish nurseries for the construction of resorts (Young 2008. Trop. Conserv. Sci 1:18–33; Chenot-Rose, pers. obs.) is perhaps forcing isopods to exploit a new dietary niche or host, i.e., the crocodiles. Interestingly, the current rise of isopod eye infections parallels the recent emergence of ocular abnormalities among crocodiles inhabiting Ambergris Caye (Chenot-Rose, pers. obs.). Further exploration into the isopod-crocodile interaction should be pursued to determine if human transformation of the islands' mangrove ecosystem is indeed forming a new host-parasite dynamic.

We thank Vince Rose and Chris Summers from the American Crocodile Education Sanctuary (ACES) for their assistance in the capture of crocodiles and collection of isopods, and Rick Brusca for the positive identification of *R. signata*. We also acknowledge Alvaro Font for providing the picture of the isopod infection of *C. acutus*.

***MELANOSUCHUS NIGER* (Black Caiman). DIET.** Many crocodilian species are known to consume fruits and seeds but diet information for some species is still lacking (Platt et al. 2013. J. Zool. 291:87–99). We captured an adult female *Melanosuchus niger* (SVL = 139 cm; total length = 255 cm; 57 kg) on 7 February 2014 near Yupukari, Guyana (3.6967°N, 59.3275°W; WGS84) and collected its stomach contents using the hose-Heimlich technique (Fitzgerald 1989. J. Herpetol. 23:170–172). While examining its stomach contents we found a partially digested seed measuring 2.7 × 2.9 cm and weighing 1.6 g. We identified the seed as coming from a tree in the Mimosoideae, a subfamily of Fabaceae. This observation constitutes the first record of seed consumption by *M. niger*, but we do not know if the seed was consumed intentionally or incidentally during other feeding activities.

Box 10-1110, Georgetown, Guyana

SQUAMATA — LIZARDS

***AMEIVULA ABAETENSIS*. SAUROCHORY.** Two essential stages in the life cycle of plants, pollination and seed dispersal, could be directly affected by animals (Godínez-Álvarez 2004. Rev. Chil. Hist. Nat. 77:569–577). Some species of lizards feed on seeds, nectar, pollen, and fruit, being considered important disperser agents (e.g., Olesen and Valido 2003. Trends Ecol. Evol. 18:177–181; Casado and Soriano 2010. Ecotrópicos 23:18–36; Gomes et al. 2014. Plant Biol. 16:315–322). Some lizards are seed dispersers of Cactaceae in Brazil. *Tropidurus cocorobensis* is considered a disperser of *Melocactus paucispinus* (Fonseca et al. 2012. Acta Bot. Bras. 26:481–492); *T. torquatus* a disperser of *M. violaceus* (Figueira et al. 1994. Biotropica 26:295–301); *T. semitaeniatus* a disperser of *M. ernestii* (Gomes et al. 2014, *op. cit.*); and *Ameivula ocellifera* a disperser of *M. glaucescens* (Fonseca et al. 2012, *op. cit.*). *Ameivula abaetensis* is a lizard endemic to the sand dune habitat ("restinga") of northern Bahia State from Salvador Municipality to Pirambu Municipality, with a disjunct population in Areia Branca Municipality, all located in Sergipe State, Brazil. The diet of this lizard species consists of small arthropods and murici fruits (*Byrsonima microphylla*) (Dias and Rocha 2007. Braz. J. Biol. 67:41–46).

On 13 and 14 April 2014 we collected two adult females of *Ameivula abaetensis* (SVL = 67.87 mm, 61.79 mm) in a fragment of "restinga" habitat (36.84364°W, 10.69363°S, WGS84; 89 m elev.), Pirambu Municipality, Sergipe State, Brazil. The lizards were captured (collection permit: 42941-1 SISBIO/ICMBio), euthanized (protocol license: 16/2014 CEUA), and deposited in the collection of the Laboratório de Biologia e Ecologia de Vertebrados / Universidade Federal de Sergipe (LABEVL578; LABEVL579). The specimens were dissected, and food items identified and counted. Among them we recorded presence of fruits of *Melocactus violaceus* Pfeiff. subsp. *margaritaceus* N. P. Taylor. Each lizard had one

fruit and a variable number of intact seeds. This is the first record of cactus fruits consumed by *Ameivula abaetensis*. Fleshy fruits of cactus are an energy source and have high water content (Figueira et al. 1994, *op. cit.*). Fruits of *Byrsonima microphylla* were recorded in the diet of *A. abaetensis*, but seeds were not found in the gut (Dias and Rocha 2007, *op. cit.*; Santa-Rosa et al. 2012. Bol. Mus. Biol. Mello Leitão 29:53–63). The presence of seeds of *Melocactus violaceus* in the gut of *A. abaetensis* is an important indicator of the role of this lizard as a disperser. Passing through the digestive tract of reptiles may increase the germination rate of seeds (Figueira et al. 1994, *op. cit.*) or may not influence seed germination (Valido and Nogales 1994. Oikos 70:403–411; Fonseca et al. 2012, *op. cit.*).

We thank Marcos Vinícius Meiado for identifying the species of Cactaceae. The Fundação Grupo Boticário de Proteção à Natureza for research grant and Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) provided a Graduate fellowship to the first author (Process no 134877/2013-6).

***ANOLIS AURATUS* (Grass Anole). AVIAN PREDATION.** On 15 November 2013, at 0902 h, KMOA observed and photographed an adult Spotted Puffbird (*Bucco tamatia*) grasping an adult *Anolis auratus* in its beak (Fig. 1). The bird was observed in municipality of Ferreira Gomes (0.903°N, 51.259861°W; WGS84), state of Amapá, North Brazil. The entire consumption of the lizard was completed in ca. three minutes, during which time the bird appeared to have no trouble swallowing. Neither the bird nor the lizard were collected. The Spotted Puffbird is an insectivorous and frugivorous bird (Sigrist 2013. Avifauna Brasileira. Avis brasilis. 594 pp.). This is the first record of predator-prey relationship in *B. tamatia* and *A. auratus*, as well as the first prey items (vertebrates; lizards) reported for the diet of *B. tamatia*.

FIG. 1. A Spotted Puffbird (*Bucco tamatia*) with an adult Grass Anole (*Anolis auratus*) in municipality of Ferreira Gomes, Amapa, North Brazil.

***ANOLIS CRISTATELLUS* (Crested Anole). DIET.** At approx. 1300 h on 23 October 2012 we observed an *Anolis cristatellus* with a lizard tail protruding from its mouth. The anole was in leaf litter next to a trail at the Guana Island Resort on Guana Island, British Virgin Islands (18.47786°N, 64.57806°W; WGS84). We captured the anole and it regurgitated its prey, an adult *Sphaerodactylus macrolepis* (Caribbean Dwarf Gecko; Fig. 1).

Anolis cristatellus are known to feed on small lizards, though species-level identification of the prey is rarely reported. Lizard species predated upon include conspecifics (Henderson and Powell 2009. Natural History of West Indian Reptiles and Amphibians. University Press of Florida, Gainesville, Florida. 496 pp.), *Anolis krugi* (Henderson and Powell 2009, *op. cit.*), *Hemidactylus mabouia* (Owen and Perry 2005. Herpetol. Rev. 36:444), and *Sphaerodactylus nicholsi* (Thomas and Gaa Kesler 1996. *In* Reagan and Waide [eds.], The Food Web of a Tropical Rain Forest, pp. 354–355. University of Chicago Press, Chicago, Illinois; López-Ortiz and Lewis 2004. Herpetologica 60:438–444). To our knowledge, this is the first report of *A. cristatellus* preying on *S. macrolepis*. Other known predators of *S. macrolepis* on Guana Island include *Borikenophis portoricenis* (Puerto Rican Racer; Henderson and Powell 2009, *op. cit.*), *Geotrygon mystacea* (Bridled Quail-Dove; Boal 2008. J. Carib. Ornithol. 21:50), and *Coccyzus minor* (Mangrove Cuckoo; Henderson and Powell 2009, *op. cit.*). Other known lizard predators of *S. macrolepis* include *Ameiva exsul* and *Anolis pulchellus* (Henderson and Powell 2009, *op. cit.*).

We thank Tracy Langkilde and the staff of the Guana Island Hotel. This research was funded by the National Science Foundation, the Invasive Animals CRC, and the Guana Island Science Program.

FIG. 1. *Anolis cristatellus* (Crested Anole) with the *Sphaerodactylus macrolepis* (Caribbean Dwarf Gecko) that it regurgitated.

CRYSTAL KELEHEAR, School of Biological Sciences, The University of Sydney, NSW 2006, Australia (e-mail: crystal.kelehear@hotmail.com); **SEAN P. GRAHAM**, Department of Biology, Geology, and Physical Sciences, Sul Ross State University, Alpine, Texas 79832, USA (e-mail: sean.graham@sulross.edu).

***BRONCHOCELA CRISTATELLA* (Green Crested Lizard). ENDOPARASITES.** *Bronchocela cristatella* (previously *Calotes cristatellus*) ranges from the Nicobar Islands of India, eastward through Myanmar and Thailand and south through Peninsula Malaysia

and Singapore, eastward through the Philippines, Indonesia and Papua New Guinea (Diong and Lim 1998. Raffles Bull. Zool. 46:345–359; Hallermann 2005. Russ. J. Herpetol. 12:168–183). To our knowledge, there are four reports of endoparasites in *B. cristatella*: Blasingam (1964. Bull. Singapore Nat. Mus. 32:103–127) reported the digenean *Paradistomum orientalis* and the nematode *Strongyluris calotis*; Fischthal and Kuntz (1965. Proc. Helminthol. Soc. Washington 32:124–136) reported the digenean *Mesocoelium sociale* and nematodes *Parapharyngodon maplestoni* and *Strongyluris calotis*; McQuistion et al. (2001. Acta Protozool. 40:71–74) described a coccidian, *Isospora bronchocelae*; and Kuzmin et al. (2012. J. Parasitol. 98:608–611 described a nematode *Rhabdias odilebaini*. The purpose of this note is to add to the parasite list of *B. cristatella*.

A sample of eight *B. cristatella* (mean SVL = 103.3 mm ± 5.3 SD, range = 97–113 mm) collected in West Malaysia during 2003–2006 by LLG and deposited in the herpetology collection of La Sierra University (LSUHC), Riverside, California, USA were examined for helminths. Lizards examined were from the following states Johor (N = 7: LSUHC 5526, 5568, 5777, 6394, 7678, 8022, 8121), and Penang (N = 1: LSUHC 6742).

The digestive tract was removed and the esophagus, stomach, small and large intestine were opened and their contents were examined for parasites utilizing a dissecting microscope. Nematodes were the only helminths found. Each was placed in a drop of lactophenol on a glass microscope slide, cover slipped and studied under a compound microscope. Four species of Nematoda were identified as: *Abbreviata deschiensi, Meteterakis singaporensis, Orneoascaris sandoshami* and *Strongyuris calotis*.

Voucher helminths were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland, USA as *Abbreviata deschiensi* (USNPC 108143), *Meteterakis singaporensis* (USNPC 108144), *Orneoascaris sandoshami* (USNPC 108145), *Strongyuris calotis* (USNPC 108146).

Three *Abbreviata deschiensi* were found in the stomach; prevalence = number infected lizards/number lizards examined × 100 = 25%, mean intensity = mean number helminths per infected lizard = 1.5 ± 0.70 SD, range = 1, 2. One *Meteterakis singaporensis* was found in the large intestine; prevalence = 13%; two *Orneoascaris sandoshami* were found, one each in the small and large intestine (note: these appeared to be spent females); prevalence = 13%; 43 *Strongyuris calotis* were found in the small and large intestine (prevalence = 100%; mean intensity = 5.4 ± 3.7 SD, range = 1–11).

Abbreviata deschiensi was described from *Calotes versicolor* from Vietnam by Van-Hoa et al. (1966. Bull. Soc. Pathol. Exot. Filal. 59:991–996). To our knowledge, *Bronchocela cristatella* is the second species to harbor it. *Meteterakis singaporensis* was described from *Duttaphrynus melanostictus* (as *Bufo melanostictus*) from Malaysia by Sandosham (1954. Stud. Inst. Med. Res. Malaya 26:210–226), and is also known from *Eutropis multifasciata* also of Malaysia (Singh 1967. Bull. Nat. Mus. Singapore 33:95–100). *Orneoascaris sandoshami* was described from *Megophrys aceras* from Kuala Lumpur, Malaysia (Yuen 1963. Parasitology 53:89–94) and is known from *Gonocephalus abbotti* (Goldberg et al. 2005. Herpetol. Rev. 36:450). *Strongyluris calotis* is a widespread nematode in lizards from Southeast Asia (Baker 1987. Mem. Univ. Newfoundland, Occas. Pap. Biol. 11:1–325). See Yildirimhan et al. 2006. (Comp. Parasitol. 73:257–262) for an updated host list. *Bronchocela cristatella* represents a new host record for *Abbreviata deschiensi, Meteterakis singaporensis* and *Orneoascaris sandoshami*.

LEE GRISMER,** La Sierra University, Department of Biology, Riverside, California 92515, USA (e-mail: lgrismer@lasierra.edu); **JEANETTE ARREOLA,** Whittier College, Department of Biology, Whittier, California 90608, USA (e-mail: jarreola@poets.whittier.edu).

***COLEODACTYLUS MERIDIONALIS*. PREDATION.** Spiders have been reported preying upon a wide variety of vertebrate taxa, particularly small lizards (Ervin et al. 2007. Herpetol. Rev. 38:468; Carbajal-Márquez et al. 2013. Herpetol. Rev. 44:505). Such predatory behavior can occur via active foraging, ambush, or by use of webs (Hamilton 2012. Herpetol. Rev. 42:603; Lanschi and Barbosa 2012. Herpetol. Rev. 43:l34: Lazcano et al. 2012. Herpetol. Rev. 43:l38).

Coleodactylus meridionalis is a litter-dwelling gekkonid lizard distributed in the tropical dry forest Caatinga and Atlantic Rainforest of northeastern Brazil (Vanzolini et al. 1980. Répteis das Caatingas. Acad. Bras Cienc., São Paulo. 161 pp.), and its small size facilitates their predation by other larger litter dwelling animals (Vargens et al. 2005. Herpetol. Rev. 36:l73–174).

On 20 December 2011 during the sampling of leaf-litter herpetofauna at 2253 h in Reserva Caju (11.19038°S, 37.31750°W; 13 m elev.), Itaporanga D'Ajuda municipality, Sergipe State, Brazil one of us (RPSA) observed a specimen of the spider *Parabatinga brevipes* preying on *Coleodactylus meridionalis* (Fig. 1). *Parabatinga brevipes* is a generalists Ctenidae species and has been recorded preying on small amphibians in the Amazon Rainforest (Caldwell and Myers 1990. Am. Mus. Novit. 2988:1–23). This is the first record of predation of *C. meridionalis* by spiders in Atlantic Rainforest and contributes to the knowledge of food webs involving small litter vertebrates.

We thank Marcelo Cesar Lima Peres for identification of the spider described in this report and Elves de Lima Alves, Tassiana Alves Maciel, and Rúbia Kelly Côrtes Rocha for assistance in collecting the specimen.

***CTENOPHORUS RETICULATUS* (Western Netted Dragon), *CTENOPHORUS CAUDICINCTUS* (Ring-tailed Dragon), and *EGERNIA EOS* (Central Pygmy Spiny-tailed Skink). PREDATION.** Clarifying the suite of predators can contribute to understanding how populations are regulated, and how predators influence the behavior of prey. Yet, the suite of predators is often poorly known for a given small vertebrate, especially in the tropics. Herein we report nine observations of predation on lizards (*Ctenophorus, Egernia*) by at least five individual Australian Kestrels (*Falco cenchroides*) in northern and western Australia.

On 15 August 2012, two of us (SC and JT) located an Australian Kestrel nest site on a rock ledge approximately 4 m high in breakaway country in the eastern Gascoyne region of Western Australia (26.135443°S, 121.341007°E). The nest was inactive but contained signs of prior use (eggshell, scats, pellets, and a few prey remains), and an adult kestrel was flushed from a roost site adjacent to the nest at the time of discovery (1040 h). Included in the prey remains were the tails of two lizards, which were identified as *Egernia eos* (Doughty et al. 2011. Rec. West. Austral. Mus. 26:115–137). The tails, which were undoubtedly not consumed due to their spines, measured approximately 50 mm, indicative of adult lizards.

At 1140 h on 11 October 2011, one of us (SC) discovered a freshly caught, dead *Ctenophorus caudicinctus* in an active Australian Kestrel nest on an ironstone ridge in the Murchison Region of Western Australia (25.814023°S, 117.337149°E). The nest was on a horizontal ledge 5 m high and 1 m deep, and contained five nestling kestrels. Lizard scales, which appeared to belong to other agamids, were observed in pellets both in and below the nest cavity. Similarly and also in the Murchison Region (27.055624°S, 118.143344°E), on 10 August 2010 one of us (JT) discovered the remains of three *Ctenophorus reticulatus* in a recently active Kestrel nest, after flushing an adult from the nest. Also in the Murchison (26.905426°S, 117.688449°E), on 28 March 2009 one of us (JT) found a live but mortally wounded *C. reticulatus* on the slopes of a breakaway at Weld Range. Just a few meters above the lizard was a second *C. reticulatus* (dead) on a ledge next to an active Australian Kestrel nest.

On 18 October 2013, one of us (SC) located an Australian Kestrel nest site in a hollow cavity 2 m above the ground in a *Eucalyptus* tree in the Gascoyne Region (26.135443°S, 121.341007°E). An adult kestrel was observed delivering a fresh prey item to the three chicks inside the nest at approximately 0715 h. Closer inspection revealed the prey animal to be a lizard, *Ctenophorus sp.* (Fig. 1). The kestrel, along with its mate, was later observed foraging over nearby chenopod habitat where *Ctenophorus salinarum* is a common species. However, we could not be certain of species identification; also present in the general area are *C. isolepis, C. nuchalis, C. reticulatus,* and *C. scutulatus.*

PHOTO BY S. CHERRIMAN

FIG. 1. A dead lizard (*Ctenophorus* sp.) lays (belly-up) next to three nestling Australian Kestrels (*Falco cenchroides*). The lizard was provided by one of the parent birds.

Although we did not observe prey capture during these observations, kestrels are generally hunters rather than scavengers, suggesting that the raptors had recently caught and killed the lizards (indeed one lizard was still alive). Lizards can comprise the bulk of the biomass in the diet of Australian Kestrels in some arid populations (Dickman et al. 1991. Emu 91:69–72; Aumann 2001. Wildl. Res. 28:379–393), but may be less important in other populations (e.g., Olsen et al. 1978. Emu 79:133–138). Congeners have been reported in kestrel pellets from arid Australia (*Ctenophorus nuchalis, C. caudicinctus, Egernia* spp., Doody and Schembri 2014. Herpetol. Rev. 45:494–495; Dickman et al., *op. cit.*; Aumann 2001, *op. cit.*). Because these small- to medium-sized lizards are an important prey group to kestrels, kestrels are likely a chief predator of the lizards. We might expect that these lizards have thus evolved antipredator behaviors to reduce predation by Australian Kestrels; observations of vigilance behavior of these lizards are needed to address this hypothesis.

Helena, Western Australia, 66082, Australia (e-mail: aquila84@iinet.net.au); **JEFF TURPIN**, 79B Mars Street, Carlisle, Western Australia, 6101, Australia (e-mail: jeff.m.turpin@gmail.com).

***INTELLAGAMA LESUERII LESUERII* (Eastern Water Dragon). TRIFID TAIL.** On 15 November 2014, a wild adult male *Intellagama lesuerii lesuerii* was captured and removed from a Southern Hairy-nosed Wombat (*Lasiorhinus latifrons*) enclosure at the Taronga Zoo, Sydney, Australia (33.85°S, 151.25°E). This individual had a trifurcated tail (Fig. 1).

Tail bi-, tri-, and poly-furcation often occurs during the regeneration process that follows autotomy (Sluys et al. 2002. Stud. Neotrop. Fauna E. 37:227–231; Galdino et al. 2006. Phyllomedusa 5:25–30), and autotomy is typically used as an anti-predator defense during a predation event (Bateman and Fleming 2009 J. Zool. 277:1–14). Within the zoo grounds, roaming wild *Intellagama lesuerii lesuerii* regularly enter enclosures and come in contact with a variety of novel domestic and exotic predators, resulting in frequent successful and unsuccessful predation events taking place. For this reason we believe that the trifid tail of this individual may have been caused by regeneration of the tail after a single, or multiple predation attempt(s). However, there is also a high degree of urbanization around the zoo grounds; as such, pollution may have caused the trifurcation of this tail through developmental deformity, similar to pollution-triggered developmental deformities seen in snakes (Gray et al. 2001. Bull. Chicago Herpetol. Soc. 36:144–148; Gray et al. 2003. Bull. Chicago Herpetol. Soc. 38:4–6; Wallach 2007. Bull. Maryland Herpetol. Soc. 43:57–95). Bifurcated tails have been reported for many lizard groups, such as Agamidae (Brindley 1898. J. Bombay Nat. Hist. Soc. 11:680–689; Ananjeva and Danov 1991. Amphibia-Reptilia. 12:343–356), Scincidae, Lacertidae, Iguanidae (Brindley 1898,

FIG. 1 An adult male Eastern Water Dragon (*Intellagama lesuerii lesuerii*) captured at the Taronga Zoo, Sydney, Australia, after climbing into a wombat enclosure (A). The individual was found to have grown a trifurcated tail (B) likely due to repeated predation attempts from wildlife living either on zoo grounds or in the surrounding suburbs.

op. cit.), and Gekkonidae (Woodland 1920. Q. J. Microscop. Sci. 65:63–100). However, to the best of our knowledge, this is the first recorded case of tail trifurcation in *Intellagama lesuerii lesuerii.*

***PLESTIODON FASCIATUS* (Five-lined Skink). DIET.** Five-lined Skinks (*Plestiodon fasciatus*) are reported to primarily ingest a variety of insects and other arthropods (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.), but earthworms, crustaceans, snails, baby mice, and small lizards have also been reported as prey (Sievert and Sievert 2011. A Field Guide to Oklahoma's Amphibians and Reptiles. Oklahoma Department of Wildlife Conservation, Oklahoma City. 211 pp.). I am not aware of previous reports of *P. fasciatus* eating any other skink species. Here I report an instance of *P. fasciatus* ingesting a Ground Skink, *Scincella lateralis.*

A sub-adult *Plestiodon fasciatus* (SVL = 50 mm) was collected by hand on 21 September 2014 from Hochatown, McCurtain Co., Oklahoma, USA (34.123155°N, 91.690684°W; WGS84). It was euthanized with an intraperitoneal injection of sodium pentobarbital (Nembutal®) and a mid-ventral incision was made to expose the viscera. On examination of stomach contents, a hatchling (SVL = 23 mm) *S. lateralis* was found (Fig. 1).

FIG. 1. Hatchling *Scincella lateralis* from stomach contents of *Plestiodon fasciatus.* Scale bar = 5 mm.

In addition, a portion of a cricket was in the stomach contents. Voucher specimens of skinks are deposited in the Arkansas State University Museum of Zoology (ASUMZ) Herpetology Collection as ASUMZ 33322, 33323.

Fourteen additional *P. fasciatus* were examined from McCurtain Co. and no *S. lateralis* were found in stomach contents. Bowie (1973. J. Herpetol. 7:318) reported an instance of a Florida Scrub Lizard (*Sceloporus woodi*) feeding on *S. lateralis. Plestiodon fasciatus* should be listed as a potential predator of *Scincella lateralis.*

I thank the Oklahoma Department of Wildlife Conservation for a Scientific Collecting Permit and S. E. Trauth (ASUMZ) for expert curatorial assistance.

***PLESTIODON FASCIATUS* (Five-lined Skink). PREDATION BY FISH.** *Plestiodon fasciatus* is a common lizard found throughout much of the eastern half of the United States and inhabits woodland and mesic habitats including near-stream environments (Gibbons et al. 2009. Lizards and Crocodiles of the Southeast. University of Georgia Press, Athens. 235 pp.). *Plestiodon fasciatus* has historically been rumored to possess a chemical defense (Fitch 1954. Univ. Kansas Publ., Mus. Nat. Hist. 8:1–156) associated with the bright blue tail (considered to be a warning color). But this potential defense has never been definitively demonstrated. Despite this putative defense, the documented list of potential predators of *P. fasciatus* includes snakes, hawks, crows, moles, shrews, and opossums (Fitch 1954, *op. cit.*). We present here the first documented occurrence of a fish consuming a *P. fasciatus.*

An individual Alabama Bass, *Micropterus henshalli,* measuring 33 cm standard length (SL) was caught by hook and line in the Cahaba River on 20 June 2014 approximately 5 km downriver (33.3755°N, 86.6761°W) from the intersection of Grants Mill Road and the Cahaba River, Birmingham, Alabama. The bass was hooked along the bank of the river in an area characterized by the presence of tree branches extending low over the water and downed trees and tree roots partially submerged in the river. The fish was consuming an adult female *P. fasciatus* that measured

FIG. 1. *Plestiodon fasciatus* in mouth and gullet of an Alabama Bass (*Micropterus henshalli*).

approximately 14 cm from snout to tail tip (Fig. 1). The skink, while completely intact, was dead, most likely from drowning. The head of the skink protruded from the mouth of the bass (Fig. 1), but the mid and lower body and tail of the skink were in the fish's gullet (JBM, pers. obs.).

Freshwater bass in the genus *Micropterus* are considered opportunistic predators that feed primarily on fish, crayfish, and a wide variety of aquatic insects. Observations of the consumption of lizards by bass have never been published in the scientific literature to our knowledge. A number of studies have examined the natural dietary habits of the Spotted Bass, *Micropterus punctulatus* (Applegate et al. 1967. Proc. Ann. Conf. SE Assoc. Game Fish Comm. 20:469–482; Smith and Page 1969. Trans. Amer. Fish. Soc. 98:647–651; Scott and Angermeiere 1998. N. Amer. J. Fish. Manag.18:221–235), the species most closely related to *M. henshalli*. These studies indicate that the primary prey types of adult fish include various species of fish, crayfish, and aquatic insects. Juvenile Spotted Bass (<7.5 cm total length) consume smaller prey comprised primarily of aquatic insects and zooplankton (Smith and Page 1969, *op. cit.*). Adult Smallmouth Bass, *M. dolomieu*, consume fish and aquatic insects and to a lesser degree crayfish (Robertson and Winemiller 2001. Southwest. Nat. 46:216–221). Adult Largemouth Bass primarily consume fish and crayfish with aquatic insects less common in the diet (Wheeler and Allen 2003. Trans. Amer. Fish. Soc. 132:438–449; Rayborn et al. 2004. Ecol. Freshwater Fish 13:276–284). Long and Fisher (2000. J. Freshwater Ecol. 15:465–474) examined diets of all three of these bass species in an Oklahoma Reservoir and found that adult Largemouth Bass fed primarily on fish, while adult Smallmouth and Spotted Bass consumed mostly crayfish and insects. None of the dietary studies cited above report the inclusion of any lizards among prey items.

There are some interesting natural history considerations pertinent to our observation. One question is: how was the skink captured by the bass? One possibility is that the skink fell off a branch or log into the river and was consumed by the bass. The other possibility is that the bass observed the movements of the skink on a branch or log near the air-water interface and leapt out of the water to capture the skink. This latter possibility is supported by the pattern of habitat utilization of this species of bass. *Micropterus henshalli* is similar to *M. punctulatus* in that it occurs in primarily riverine habitats and prefers river banks where it exploits woody debris and bank vegetation as cover (Scott and Angermeier 1998, *op. cit.*). This would place it in close proximity to invertebrates and vertebrates that perch on branches, sticks, roots, and tree trunks.

The present study adds further evidence that the putative chemical defense of *P. fasciatus* failed to protect the skink from predation from another group of vertebrates. Clearly the tail did not inhibit consumption by *Micropterus henshalli*, nor did the capacity of the skink to autotomize its tail as a predator diversion tactic. In all likelihood, the skink was ambushed by the bass and loss of the tail would have come too late to serve as an effective diversion as it might have against more visual predators such as birds and small mammals.

***PODARCIS MURALIS* (Common Wall Lizard). COMMUNAL NESTING.** Ovoposition strategies vary among species and even within the same species. One of these strategies is communal nesting. The "constraint" (nests with optimal conditions for laying eggs are scarce) and the "adaptation" (a fitness benefit due to egg aggregation) are two reasons why female lizards lay their eggs in communal nests (Rader and Shine 2007. J. Anim. Ecol. 76:881–887). In the Iberian Peninsula, communal nesting has occasionally been reported in the species *Psammodrommus algirus, Podarcis bocagei*, *Iberolacerta aranica*, and *Zootoca vivipara* (Braña 1996. Oikos. 75:511–523; Galán 2009. Bol. Asoc. Herpetol. Españ. 20:2–34; Pleguezuelos et al. 2004. Amphibia-Reptilia 25:333–336).

In July 2013 we observed a communal nesting of *Podarcis muralis* with five clutches in a pathway close to Torla, Huesca, Aragón, Spain (42.64207°N, 0.074998° W; WGS84). The total number of eggs were 10. Nine of the eggs were intact and one was empty, suggesting that this had already hatched. They were under a stone of approximately 30 cm length, 25 cm width, and 25 cm depth. The stone was surrounded by grass and piled pieces of limestone, but nearby we could see plant species like *Pinus uncinata* and *Echinospartum horridum*. Eggs laid under large stones may benefit from stable environmental conditions for incubation. Climatic conditions in 2013 were particularly cold in the north of Spain. Normally, mating and egg-laying in *P. muralis* occurs from April to July, but in 2013 some high altitude regions remained with snow until late July. In addition, people frequently traverse the area where the communal nesting was observed. The unfavorable environmental conditions and the settlement of a nest site beside such a well traversed path may suggest that the choice of location was due to the lack of optimal oviposition sites, rather than the benefits of aggregation. Thus, the nest place was probably chosen because it offered protection against inclement weather and predators due to the stone size.

Mountain species are more vulnerable to processes associated to climate change (Sinervo et al. 2010. Science 328: 894–899). Monasterio et al. 2013 (Zoology 291:136–145) hypothesized that climate change may affect oviposition in some lizard species, as it may be in this case, inducing communal nesting. However, sorting out among constraint hypotheses requires experimental approaches. On the other hand, Gosá and Bergerandi 1994 (Munibe 46:109–189) mentioned communal nesting of *P. muralis* in Navarra, Spain. To our knowledge, this is the first description of the number of eggs and location of a communal nest in *P. muralis*. Communal nesting seems to be a common behavior in

lacertids, observational data on communal egg-laying are scarce in general and, in particular, for this species.

We are grateful to A. Lozano for her comments in the manuscript.

***PTENOPUS KOCHI* (Koch's Barking Gecko). DIURNAL ACTIVITY.** Geckos in the genus *Ptenopus* are considered to be crepuscular and nocturnal lizards that normally ambush prey from their burrow entrances, although in some regions of southern Africa *Ptenopus garrulus* (Common Barking Gecko) has been reported to become diurnally active on rainy or overcast summer afternoons when their termite prey are swarming (Huey and Pianka 1981. Ecology 62:991–999). Little information is available on the Namib Desert endemic *P. kochi*. Here we document the first reported cases of diurnal activity in this species. On 26 June 2014 between 1030–1312 h we encountered five juvenile *P. kochi* active on gravelly-sand substrates in an interdune region south of the Kuiseb River at Gobabeb Research and Training Centre, Namibia (23.57903°S, 15.03838°E; WGS84), 411 m elev. In the same area we documented an additional juvenile *P. kochi* active on the surface at 1144 h on 5 July 2014. This individual was 24 mm SVL, weighed 0.50 g, and had an 18 mm-long original tail. Although we did not weigh or measure the first five geckos, they all appeared similar in size to the measured gecko. Both mornings had started out cloudy and cool, but five out of the six geckos noted here were active in the full sun. The clouds had cleared by 1112 h on 26 June and by 0806 h on 5 July. Mean cloacal temperature within seconds of capture was 28.7 ± 1.1°C (range 25.4–30.0°C; N = 4), the air temperature 10 mm above the surface where geckos were observed active averaged 25.6 ± 0.8°C (range 24.0–28.0°C; N = 5), and the surface temperature where geckos were located averaged 30.7 ± 1.0°C (range 27.0–32.9°C; N = 5). In three of the cases, no burrows were visible near the active geckos. In one case the gecko was active ca. 20 cm away from the closest burrow. Two of the observed geckos were located ca.1 m from the closest burrow, and when startled one of these individuals immediately fled straight to this burrow. It is possible that these geckos were actively foraging during daylight, outside of their burrows, but we did not observe any swarming termites active near any of the geckos, and we did not observe any larger juvenile or adult *P. kochi* diurnally active. Instead, we hypothesize that these were all post-hatchling geckos that may have been dispersing away from the burrows that they hatched in. Hatchlings of the closely related and slightly smaller *P. garrulus* are ca. 22 mm SVL (Hibbitts et al. 2005. J. Herpetol. 39:509–515), which is a close approximation to the sizes we observed, supporting the notion that the *P. kochi* seen here had recently hatched. These observations contribute to the dearth of information available on the ecology of *P. kochi*, and prompt further questions about the dispersal of juvenile geckos away from their natal burrows, and whether or not they construct their own burrows or use pre-existing burrows.

We thank Gillian Maggs-Kölling and Theo Wassenaaar of Namibia's Gobabeb Research and Training Centre as well as the Brain Function Research Group at the University of the Witwatersrand for support and the Namibian Ministry of Environment and Tourism for permission to work in the Namib-Naukluft National Park.

IAN W. MURRAY (e-mail: Ian.Murray@wits.ac.za), **HILARY M. LEASE**, Brain Function Research Group, School of Physiology, Faculty of Health Sciences, University of the Witwatersrand, Parktown, 2193, Johannesburg, South Africa.

***SALVATOR MERIANAE* (Tegu). DIET.** *Salvator merianae* is a teiid lizard widely distributed in Argentina, Uruguay, Bolivia, and Brazil. The diet of this lizard is mainly composed of fruits, flowers, invertebrates (such as spiders, crustaceans, and insects), small vertebrates, eggs, and decomposing animals (Kiefer and Sazima 2002. Amphibia Reptilia 23:105–108). Records of predation on vertebrates consist of other lizards, such as *Tropidurus hispidus* (Silva et al. 2013. Herpetol. Notes 6:51–53), *T. torquatus* (Arruda et al. 2007. VIII Congr. Ecol. Brasil. 1–2), and the bird *Turdus leucomelas* (Santos and Vaz-Silva 2012. Herpetol. Brasil. 1[1]:35–36).

We observed two cases of predation by *S. merianae* in different domains. The first observation was made during the collection of lizards in an area of Caatinga, in Sítios Novos (9.80500°S, 37.68444°W), Municipality of Poço Redondo, Sergipe State, Brazil. On 10 January 2012, an individual was seen preying on an anuran, *Rhinella granulosa* (SVL = 58.83 mm). The second record is from the Atlantic Forest, in the Refúgio de Vida Silvestre Mata do Junco (10.53972°S, 37.06194°W), Municipality of Capela, Sergipe, State. On 25 January 2013, a young individual (SVL = 22.27 cm; 320 g) was collected and regurgitated a frog, *Leptodactylus natalensis* (SVL = 15.32 mm), and two orthopterans with volumes of 0.0014 and 0.0004 mm^3, respectively (ellipsoid formula). The voucher specimens of *R. granulosa* and *L. natalensis* and the second individual of *S. merianae* were preserved in alcohol and deposited in the collection of Laboratório de Biologia e Ecologia de Vertebrados of the Universidade Federal de Sergipe (LABEVA 862; LABEVA 1129 and LABEVL 408, respectively). This is the first record of *Rhinella granulosa* and *Leptodactylus natalensis* being included in the diet of *Salvator merianae*, and it can help in understanding the trophic food webs of these groups.

***SCELOPORUS CYANOSTICTUS* (Yarrow's Blue-spotted Spiny Lizard). FIELD AND PREFERRED BODY TEMPERATURE.** Monitoring thermal requirements and thermoregulatory behavior of reptiles is crucial for understanding effects of global warming on species (Sinervo et al. 2010. Science 328:894–899). *Sceloporus cyanostictus* is an endangered species endemic to Mexico (www.iucnredlist.org; 9 Oct 2014), with a geographically restricted distribution and little variation in habitats occupied (Gadsden et al. 2006. Bull. Chicago Herpetol. Soc. 41:2–9; Lemos-Espinal and Smith 2007. Amphibians and Reptiles of the State of Coahuila, Mexico. UNAM-CONABIO. 550 pp.). There have been reports detailing the field body temperature of *Sceloporus* lizards (e.g., Andrews et al. 1997. Copeia 1997:108–115), although data on T_p (preferred temperature) within this genus are not usually reported (Mathies

and Andrews 1997. Funct. Ecol. 11:498–507; Lara-Reséndiz et al. 2014. Rev. Mex. Biol. 85:875–884). Field body temperature and preferred body temperature has not been documented in *S. cyanostictus*. Here, we describe field body temperature and thermal preference under laboratory conditions for this species.

During September 2009, we conducted fieldwork in Sierra San Lorenzo (25.651103°N, 103.172353°W, WGS84; 1146 m elev.), 15 km NE Matamoros, Coahuila, Mexico. Vegetation was dominated by *Yuca filifera, Agave lechuguilla, Fouqueria splendens, Opuntia rufida*, and *O. rastrera*. Throughout the study site, rock faces with crevices were numerous. The data presented are based on 33 adults (> 60.0 mm SVL; 18 females and 15 males) of *Sceloporus cyanostictus* captured by noose. The field body temperature (T_b) of each lizard captured was measured using a digital thermometer (Fluke™ model 51-II) with a thermocouple inserted into the cloaca.

In the laboratory, the lizards were separated by gender and maintained at 25°C in plastic containers with 2 cm of rocky ground and hydrated with sprinkler. Laboratory experiments were conducted two days after capture using a thermal gradient. The thermal gradient consisted of a wooden shuttle box of 150 × 100 × 80 cm (length, width and height) divided into ten tracks with insulation barriers to prevent behavioral influence of adjacent lizards, and filled with 2–3 cm of rocky ground. The shuttle box was housed in a room with air conditioning at a constant temperature of 20°C. At one end, and at the center of the box, lamps were placed at different heights to generate a thermal gradient from 20 to 50°C. The T_p of lizards was measured every hour from 0900 until 1800 h (foraging activity period) using a digital thermometer. The 25% and 75% quartiles of T_b in field (T_{b25} and T_{b75}) and T_p in laboratory (T_{p25} and T_{p75}) ranges were calculated to obtain the lower and upper limit (Van Damme et al. 1990. Oikos 57:61–67; Herts et al. 1993. Am. Nat. 142:796–818). After laboratory experiments, all lizards were released at their capture sites. We applied a nonparametric Kruskal-Wallis one-way test (denoted H) to analyze differences between all measurements of T_b and the same test to analyze differences between all measurements of T_p, also we used a Mann-Whitney Rank test to analyze the differences between gender.

There were no statistically significant difference between measurements of T_b (the observed value $H_1 = 0.52$, P = 0.46 was less than the critical value) or T_p (the observed value $H_{16} = 20.47$, P = 0.20 was less than the critical value). Also there were no statistically significant difference between gender in T_b (U = 286.0, P = 0.48). Mean T_b for males was 32.58°C (SE = 0.67, range = 29–38.1°C; N = 15); interquartile of 25% and 75% was 29.8 and 34.6, respectively. Mean T_b for females was 31.52°C (SE = 0.66, range = 22–35.2°C; N = 18); interquartile of 25% and 75% was 30.5°C and 33.4°C, respectively. However there were statistically significant difference between gender in laboratory (U = 9524.5, P = 0.03). Mean T_p for males was 32.37°C (SE = 0.27, range = 24.4–36.8°C; N = 110); interquartile of 25% and 75% was 30.2 and 34.6, respectively. Mean T_p for females was 33.2°C (SE = 0.31, range = 26–38.4°C; N = 76); interquartile of 25% and 75% was 32.0°C and 35.2°C, respectively. The field body temperature and preferred body temperature of *Sceloporus cyanostictus* were very similar to those previously recorded for other closely related species of *Sceloporus torquatus* species-group (Andrews 1998. J. Therm. Biol. 23:329-334; Martínez-Méndez and Méndez de la Cruz 2007. Zootaxa 1609:53–68).

These results suggest that *Sceloporus cyanostictus* can be considered a eurythermic species due to its wide range of T_b and T_p. Therefore, we propose to evaluate the thermal efficiency by monitoring mean thermal requirements and microhabitat temperatures across its distribution for understanding effects of global warming on this geographically restricted lizard.

HECTOR GADSDEN, Instituto de Ecología, A. ***SCELOPORUS GRAMMICUS* (Mesquite Lizard). PURSUIT-DETERRENT SIGNALING.** Tail waves and tail barring patterns in *Cophosaurus* and *Callisaurus* lizards are hypothesized forms of pursuit-deterrent signals (Dial 1986. Am. Nat. 127:103–111; Hasson et al. 1989. Can. J. Zool. 67:1203–1209). *Anolis* lizards perform push-ups and dewlap extensions as pursuit-deterrent signals directed toward snakes and snake models (Leal and Rodríguez-Robles 1997a. Anim. Behav. 54:1147–1154; 1997b. Biotropica 29:372–375), and the displays may serve as honest signals of a lizard's ability to escape predation (Leal 1999. Anim. Behav. 58:521–526). Here, we report two observations of male *Sceloporus grammicus* displaying to snakes that prey on lizards (Ramírez-Bautista et al. 2009. Herpetofauna del Valle de México: Diversidad y Conservación. Universidad Autónoma del Estado de Hidalgo UAEH – Comisión Nacional para el Conocimiento y Uso de la Biodiversidad CONABIO, México. 213 pp.). Both observations were made under natural conditions in the breeding season of a *S. grammicus* population located ca. 1.5 km NW of Nopala, Hidalgo, México (20.26152°N, 99.63414°W, WGS84; 2482 m elev.).

On 9 October 2014, two of us (JAP and JJZV) were observing a male *S. grammicus* basking on a rock wall. We were ca. 8 m away from the lizard and had observed it for approximately 3 min before the lizard moved ca. 1.5 m in a direct line toward a large (ca. 1 m SVL) *Pituophis deppei* that was crawling along the base of the rock wall. The lizard approached the snake to within ca. 3 m and performed several displays. The displays included full-shows (dewlap extension, arched back, and dorsolateral flattening that exposes colorful abdominal patches) with four-leg push-ups (repeated elevation of the body on all four limbs) and two-leg push-ups (repeated elevation of the body on the front two limbs) without full-shows. The snake was disturbed by the observers and retreated into the rock wall. The lizard moved to the top of the rock wall and remained exposed but ceased performing displays.
